surveys participating research teams had to comply with standardized procedures for sampling, measurements and data collection. These procedures have contributed to the cross-national comparability of the data within each study.

There is a risk of selection bias, in some countries because school attendance is low and only children that attend school are respondents, and in all countries because some students were absent from school at the day of data collection or did not respond to the questionnaire. In countries with high school attendance it is likely that students who were victims of bullying were over-represented among the non-participants, i.e., the prevalence levels may be underestimated. In countries with low school attendance, it is difficult to estimate the effect of any selection bias. If most bullying in these countries takes place at school, non-attendance may be protective to bullying. However, school attendance may give the students a higher status in the local community and behavioural patterns including bullying may disseminate between school and local communities, so that children not attending school in these countries are at even higher risk of being bullied.

The measurement of bullying in the two surveys is not identical. The HBSC questionnaire asks about bullying at school and the GSHS questionnaire about bullying in general. However, the wide variation in prevalence across both surveys may indicate that the two measures of bullying victimization may not lead to very different prevalence estimates, maybe because children asked about bullying in the school setting give answers that are mostly related to the school setting, whether this specific setting is mentioned in the question or not. We have not been able to find studies that study the validity and comparability of these two measurements on the same population.

Further, the translation of questions concerning bullying into many different languages may result in information bias. The notion and severity of the concept of bullying may vary by cultural setting and is probably evidenced in some of the variability observed across countries. Nevertheless in all countries, bullying behaviour represent some sort of negative social interaction. And our earlier studies have shown remarkably stable associations between bullying and a range of physical and psychological symptoms across 28 countries of great cultural diversity (18), results that are supported by recent studies from countries like India and Namibia (19,29). Also, despite possible information bias, the association between bullying and a range of behavioural factors seem to be comparable across studies from different countries (19,20,24,29).

As stated above, the international differences in bullying levels may be based partly on cultural difference in reporting. Also the bullying concept may be perceived to cover more severe interaction in the translation into some national languages than others. This, however, is not likely to explain all international variations. For instance in the Scandinavian countries the term bullying is translated into the same word, and regardless we find very large discrepancies between these countries in the level of bullying. The national differences in policies, in school systems and school environment may account for another part of the differences, and we would welcome studies that explore how much of the differences in bullying prevalence can be explained by such differences at the national and organisational level.

Intervention programmes have demonstrated an effect on diminishing bullying within the school environment (3,37). The most comprehensive work has been performed by Olweus (2,3), who has pointed out the importance of intervening at different levels to successfully diminish the level of bullying in the school environment, and a recent review have confirmed that school-based interventions that involve multiple discipline and a whole-school approach

are most successful in reducing bullying (36). Interest and engagement at the school level is a predisposition for any successful intervention, and knowledge of the actual level of bullying at the school is an important motivational factor. The most important tool for diminishing bullying is addressing the school environment. It is recommended that the problem be highlighted for teachers and pupils by special work sessions and that it be made harder to actually perform the behaviour by increasing inspection in breaks and at other occasions, when bullying is likely to occur. At the class level Olweus highlights the importance of creating mutual behavioural norms among the group of children, for instance by letting the pupils themselves define rules for acceptable social behaviour in the group. Regular discussions in the group on how these rules are observed are essential, as are discussions at parent meetings to assure support from the home environment of the children. Olweus recommends effective interventions be directed first and foremost at the environmental level. However, for the individual involved both as victim, offender or both he recommends talks and coaching with the children as well as their parents (2).

Fairly consistent evidence suggests that children's bullying behaviour can be significantly reduced by well-planned interventions (36). The effect of relatively simple intervention tools against bullying should become known and used in countries with high prevalence of bullying, including in African schools, where intervention tools should be adapted to the cultural setting.

A recent study involving three university populations from Japan, South Africa and the US suggest that physical child harm in the families may be another important factor related to children's bullying behaviour (37).

They conclude that children that were not physically harmed by a family member in their childhood had the lowest risk of being involved in bullying of any kind as children. These results suggest that changes in societal norms on violence against children in families may be another important way to influence bullying prevalence, but the results from the study needs to be verified by other studies.

Bullying behaviour is a violation of the Convention on Rights of the Child.¹ Article 19 in The Convention express that 'States Parties shall take all appropriate legislative, administrative, social and educational measures to protect the child from all forms of physical or mental violence, injury or abuse, neglect or negligent treatment, maltreatment or exploitation, including sexual abuse, while in the care of parent(s), legal guardian(s) or any other person who has the care of the child.' And in article 28 of the Convention: 'States Parties shall take all appropriate measures to ensure that school discipline is administered in a manner consistent with the child's human dignity and in conformity with the present Convention.'

All countries involved in this study have signed the Convention on the Rights of the Child, and all countries, except the US have ratified the convention. Switzerland and the United Arab Emirates were the last countries from this study to ratify the convention in 1997. Our study suggests that very many countries that have signed the Convention on the Rights of the Child need to work much harder to live up to its goals.

This means working to intervene in schools to reduce the high prevalence of bullying, but possibly also to constitute or improve general legislations and norms for, how to treat children in our communities.

ACKNOWLEDGEMENTS

We thank Jorge C Srabstein, MD for inspiration and invitation to write this chapter and Mogens Trab Damsgaard for help with the figures. We thank all the Principal Investigators from The Health Behaviour in School-Aged Children survey (HBSC) and The Global School-based Students Health Survey (GSHS) for use of their results.

Chapter 79

PSYCHIATRIC CONDITIONS ASSOCIATED WITH BULLYING

Kirsti Kumpulainen*, MD

Department of Child Psychiatry, Kuopio University Hospital, Kuopio, Finland

ABSTRACT

Bullying is a complex phenomenon moderated by the personal characteristics and behavioral traits of the individual, but also by family rearing practices, as well as by situational factors such as the frequency and type of bullying. The phenomenon is also affected by group processes among the individuals present during the event. Bullying is a distressing experience that is often continuous over years and predicts both concurrent and future psychiatric symptoms and disorders, even in adulthood. At young ages, ADHD and depression as well as anxiety are prevalent concurrently with bullying among the children involved. Later in young adulthood male victims are at risk for anxiety, male bullies for personality disorders, and male bully-victims for both personality disorders and anxiety, and the risk is especially increased, if the child is disturbed when involved in bullying at school age. Rarely does any single behavior predict future problems as clearly as bullying does, and additional assessment of psychiatric problems is always warranted, if the child is involved in bullying as a bully, victim or bully-victim. Based on our current knowledge, school-based interventions regulating the behavior of the child, increasing prosocial skills and promoting peer relationships are recommended for those without concurrent psychiatric disturbance, but those displaying psychiatric symptoms and disorders should be referred for psychiatric consultation and intervention.

INTRODUCTION

Bullying behaviors are complex phenomena. The significance of peer relationships in bullying is clear (1) and everyone present when bullying behaviors occurs has impact to the actual situation (2). A large number of studies have shown that when bullying behaviors take

* Corresponding Author's Email: kirsti.kumpulainen@kuh.fi.

place, the roles of the individuals present can be defined according to their behaviors (3). Some are actively involved as a bully, a victim, a defender of the victim, or a reinforcer or assistant of the bully, while others play more passive roles as bystanders or outsiders, but generally all the persons present moderate the bullying by their own behavior (2,4) leading to a very complex social situation, which is a challenge for all concerned. As bullying behaviors frequently take place at school (5-6), this challenge is commonly confronted by school professionals, especially teachers but also other staff working at schools such as school health professionals.

Over the last 25 years certain personal characteristics and behavioral traits have been found to be associated with bullying behaviors. Victims have been found to be shy, silent, fearful, anxious, physically weak, insecure or in some way 'different', to cry easily and to have low self esteem (7-11), while bullies are reported to be domineering towards their peers, hostile, disruptive, and aggressive, to feel little empathy with victims and to have difficulties in concentration (1,7- 8,12-13). A common feature of both bullies and victims seems to be an inability to handle their emotions effectively. Certain problems also seem to predispose the child for bullying, such as stuttering (14), overweight and obesity (15).

However, earlier studies aiming to clarify the characteristics of children with bullying behaviors have not studied children, who bully and also are bullied as a separate group, and only during the last decade has information become available about these children, who seem to constitute the most troubled group of those involved (16-19).

CONTINUITY AND THE IMPACT OF BULLYING BEHAVIORS ON CHILDREN

The impact of bullying on children is affected by several factors. These include the personal characteristics mentioned above, but family factors, especially certain child rearing practices, also seem to be important. Overprotective, intrusive parenting and parental psychological control have been found to be related to the risk of becoming a target of bullying (20). On the other hand, lack of parental involvement, supervision and nurturing or inconsistent authoritarian parenting are connected to becoming a bully (21-22). Interparental violence and parental maltreatment have also been found to be associated with bullying and victimization (23-24). On the other hand warm family relationships and positive atmosphere at home are reported to protect the children from the negative outcomes of being bullied (25). However, there are also reports that parenting and interparental relationship are unrelated to bullying and victimization (26-28). Findings concerning bullying, parenting and family relationships are by no means conclusive and this area of research warrants further studies.

Situational factors also have major impacts on the effects of bullying. The longer the period during which the child is involved, and the more severe these behaviors, the more serious will be the consequences that most probably follow (28-29). The continuity of bullying behaviors among children has been shown. Already in 1992, Boulton and Underwood (30) reported that bullying is a generally stable behavior, lasting one year or more, and the stability is seen especially among boys. Later studies have reported stability over a period of one or two years (9-10,31). In a study concerning 1,268 children, the continuity of the involvement in bullying was shown over four years (16) and later over seven years, covering the period from childhood to middle adolescence (32). The continuity was especially prevalent among bully-victims, and

males were more prone to stay involved than were females, as also were children from low SES families.

Sourander and colleagues (33) also found bullying behaviors to be persistent over an 8-year period. They reported interesting gender differences in their sample of 898 children. In their study, almost all the boys who were victims at age 16 had been victims already at age 8, but among girls only half of those who were victims at age 16 had been victimized at age 8 years. Among bullies, the continuity was less clear: among boys, half of the bullies at age 16 had been bullies already at age 8, whereas the corresponding figure among girls was one fourth. It seems then that females are in a more favorable situation as far as staying involved in bullying over several years.

Recent research has also suggested that genetic factors play a part when the impact of bullying is considered. Sudgen with her colleagues (34) showed that the variation in the serotonin transporter (5-HTT) gene impact the risk of the development of emotional problems when facing bullying. This genetically influenced response was also related to the frequency of bullying experience. Benjet et al. (35) have also reported the interaction of serotonin transporter gene and depression among adolescent girls when they experience relational bullying. Genetic research concerning psychiatric problems is still in its infancy and further research is needed. However, the results suggest that unfavourable outcomes of bullying are likely to be also genetically influenced. Findings support the diathesi-stress model of emotional problems and could explane why some children develop emotional problems and some do not develop any such problems although they seem to face similar adversities.

BULLYING AND CONCURRENT PSYCHIATRIC SYMPTOMS AND DISORDERS

A large cross-sectional study conducted in 25 countries indicated that involvement in bullying was associated with poorer psychosocial adjustment, showing that bullies, victims, and bully-victims consistently reported greater health problems and poorer emotional and social adjustment than non-involved children (36). Another international comparative cross-sectional study in 28 countries of 123,227 students aged 11, 13 and 15 years showed that the risk of high symptom load increased with increasing exposure to bullying (29). In this large-scale study, both physical symptoms such as headaches, stomach aches, backache, and dizziness and psychological symptoms such as bad temper, feeling nervous, and sleeping difficulties were more likely to be present in bullied children. In a later study, Srabstein et al. (37) reported that involvement in bullying was associated with poor health status in a sample of 15,686 students in grades 6 to 10. In their study, several weekly occurring psychosomatic symptoms were associated with being a victim but also with being a bully or a bully-victim. According to their results, the association between bullying behaviors and health problems increased with the number of morbidities reported.

Children with several childhood problems (stuttering, overweight, intellectual disabilities etc.) have been found to be at significantly higher risk of being involved in bullying behaviors and having psychiatric symptoms. In a school-based sample of 4,746 adolescents in grades 7 to 12, teasing about body weight was consistently associated with low body satisfaction, low self esteem, high depressive symptoms, and thinking about and attempting suicide, even after

controlling for actual body weight which indicates how harmful this kind of intimidation defined as 'only teasing, not bullying' can be during the adolescent years (38). A few years ago, Blood and Blood (14) have reported an association of stuttering and self-reported anxiety, and hypothesized a bidirectional relationship between these. Reiter and Lapidot-Lefler (39) suggested that victims with intellectual disabilities have emotional and interpersonal problems, and bullies and bully-victims with intellectual disabilities display higher levels challenging behaviors such as temper tantrums, being quarrelsome and having a tendency to lie and steal.

Psychiatric symptoms and deviance have consistently been found to be associated with bullying (11,16,19,32,40-41). Bullying behaviors and psychiatric symptoms have been found to co-exist already at young ages (11). The association of bullying and psychiatric symptoms remains similar when different informants such as parents or teachers report the child's symptoms and also when children and adolescents themselves rate their psychiatric and psychosomatic symptoms (11,32).

Depressive symptoms, feeling low and nervous, having difficulties in sleeping and anxiety have been found to be common among youngsters involved in bullying in many studies (11,37,42,43-44). In particular, victims are prone to have depressive symptoms and psychological distress (32,45). However, in most studies evaluating the relationship of bullying and depression, e.g., a study of 16,410 secondary school pupils aged 14 to 16 years, both adolescent-bullies and those victimized were at an increased risk of depression and suicide (42-44). Similar findings have been reported by Klomek et al. (46), indicating that adolescents subjected to frequent exposure to victimization or bullying others are at higher risks of depression, ideation, and suicide attempts than are adolescents not involved in bullying. In their study even infrequent involvement was related to increased risk of depression and suicidality, especially among girls. In a study involving 9,863 adolescents, adolescents who were frequently involved in bullying, either as perpetrators or victims, were more than twice as likely to have depressive symptoms as their counterparts who were not involved in bullying (47). A meta-analysis of research concerning victimization and concurrent psychosocial maladjustment found a stronger association of bullying with depression than with anxiety, loneliness or general self esteem (45). The findings of this meta-analysis strongly suggest that victims experience more negative affect and negative thoughts about themselves than do other children. Suicidal tendencies and actual suicides have been found to be clearly associated with bullying in several studies (42,46, 48), and this topic will be addressed in more detail in this book.

Although internalizing symptoms, including depression and anxiety, are prevalent in bullies, numerous studies reported that they displayed especially externalizing and aggressive behaviors (9,11,49). Fighting and other violent behaviors were common among them (50). On the other hand, repeatedly bullied children can also be violent and this can have fatal consequences, as several incidents of school shootings during the last ten years have shown, when individuals who have been targets of bullying, mostly for longer periods, have attacked their peers and teachers at school and killed or injured many.

When comparing children involved in bullying, there are many reports that bully-victims are the most troubled group (11,26,37,42-43,46, 48). Bully-victims are reported to display high levels of physical and verbal aggression and to score high on emotional symptoms (13,51-52). In a large epidemiological study of 5,813 children aged 8 years (11) bully-victims displayed most psychiatric symptoms and had the highest rates of behavior disturbance compared with other groups of children (bullies, victims and non-involved children), and this finding was shown on measures using different informants (parents, teachers and children themselves).

Externalizing behavior and hyperactivity were especially related to bully-victims, and these children also expressed most depressive symptoms themselves. Wolke et al. (53) also found bully-victims to be the most behaviorally disturbed group in a study of 6- to 9-year-old children. In their study, bully-victims were 2.7-fold more likely to have any behavior problems, 3.4-fold more likely to be conduct disordered, and 2.5-fold more likely to be hyperactive than non-involved children. In addition, depression has been reported to occur especially among individuals who both bully and are bullied (42-43).

In a sample involving 423 parents and 420 children aged 8 years, most of the children involved in bullying had a psychiatric disorder (54). In particular, the disorders were common among bullies (70.8%) and bully-victims (67.1%). In this sample of 8 year-olds the most common diagnosis among children involved concurrently in bullying was ADHD, and secondly depression. Of the bullies, as many as almost one third had ADHD. One in five of bully-victims had ADHD, and ADHD was also the most common disorder among victims (14.4%). Depression was found especially in bully-victims, followed by bullies and victims. The only disorder more prevalent in victims was anxiety. These results most probably describe the situation at younger ages and it is very probable that at later ages victims have more depression and anxiety than found in this elementary school age sample, as is suggested by several studies using questionnaires as methods to evaluate bullying and concurrent psychiatric symptomatology (17) or bullying and later psychopathology (40).

The age at the time of bullying may be important regarding concurrent and later psychiatric symptoms, as children who are victimized in early teen age seem to be especially at risk of having psychiatric symptoms in later years (32,55). It has been suggested that early adolescence is a period when children are especially vulnerable to bullying, and that bullying is intense and repetitive at that age (55). However, our knowledge about the more specific impact of the age (when one is a bully, a victim or a bully-victim) on the future outcome is still scanty and warrants further research. That adolescence is a vulnerable period is also suggested by Campell and Morrison (56), who studied the relationship between bullying and psychotic-like experiences and appraisals in 14-16-year-olds, and found in a sample of 373 adolescents that bullying was significantly associated with a predisposition to psychotic experiences.

They also reported that negative post-trauma cognitions were associated with predisposition to psychotic phenomena, as were positive beliefs about paranoia. They suggested that being bullied at school and beliefs about trauma and psychotic symptoms might contribute to the development of psychosis. An association between bullying and psychotic symptoms is also reported among 12 year olds by Arseneault et al. (57). Lataster and colleagues (58), with a general population sample of 1,290 adolescents at the age of 14 years, reported that non-clinical psychotic experiences were strongly and independently associated with both bullying and sexual trauma. They suggest that the traumatic experiences of victimization may feed cognitive and biological mechanisms underlying the formation of psychotic ideation, and that adult psychosis can be understood in a developmental framework of onset of at-risk mental states in early adolescence.

BULLYING AND LATER PSYCHIATRIC SYMPTOMS AND DISORDERS

Smith and Myron-Wilson (59) pointed out less than a decade ago that only recently has attention begun to focus on the specific problems caused by bullying. However, very few studies so far have evaluated bullying and future psychiatric disorders using diagnostic interviews or longitudinal prospective methods, and no larger studies have been carried out in patient populations. Findings reported by Kim et al. (18) suggested that there is a causal effect of bullying experience on the later development of psychopathological behaviors. In their study, most forms of new-onset psychopathological behaviors at follow up (follow-up period of 10 months) were associated with antecedent bullying experiences. There are also increasing data showing long-term associations of childhood bullying and future psychiatric symptomatology and also poor outcome in many different domains of life in later years (32,40,43,60-61).

Some studies of bullying and future psychiatric disorders in adulthood have used retrospective methods. But retrospective studies have several limitations, such as recall bias, that have to be taken into account when interpreting the results, and in general a cautious attitude towards the findings is recommended. However, at present few prospective studies exist so in some areas our knowledge is based on findings generated by retrospective studies. Fosse and Holen (60) reported long-term consequences of bullying in their sample of 107 consecutive adult psychiatric female outpatients who were screened for eating disorders. They found that females with bulimia nervosa in adulthood had experienced far more bullying by peers than had others. However, other childhood experiences associated with bulimia nervosa in adulthood were also involved, such as coldness and overprotection from fathers, and more childhood emotional, physical and sexual abuse. Jordanova et al. (62) reported in their large representative sample of 8,580 participants aged 16-74 years that bullying was one of the lifetime stressors (occurring most likely during childhood or adolescence) that was significantly associated with common mental disorders such as depression and generalized anxiety, and the strength of association did not vary substantially across the age range of the sample.

Early reports concerning an association of bullying and psychiatric disorders, e.g., Olweus (63), found that males who had been victimized at school age were more depressed a decade later. Only recently, using a large prospective epidemiological sample, have associations of childhood bullying behaviors and psychiatric morbidity many years later in early adulthood among males been documented (61). In this study, adult psychiatric morbidity was assessed as part of the medical examination of military recruits and twice during the military service using the ICD-10 classification. When the status of bullying of these males at the age of 8 years was studied, most bully-victims (97%) and bullies (80%) and half of victims (50%) scored high on the Rutter scale, indicating co-existent morbidity at the elementary school age. One third of bully-victims, 18% of bullies and 17% of victims, and only 9% of those who were uninvolved at the age of 8 years, had a psychiatric disorder more than ten years later. Bully-victim status at early school age predicted both antisocial personality disorder (OR=3.9) and anxiety disorders (OR=5.2). Males who were bullies at age 8 years were more likely to have antisocial personality disorder (OR=2.9), whereas males who were victims were at risk for anxiety disorders (OR=2.6) in early adulthood. When bullying status and scoring positively on psychiatric symptomatology at age 8 years were simultaneously taken into account, males who were bully-victims with a high number of psychiatric symptoms had a 5-fold risk for a

psychiatric disorder compared with noninvolved children who had a low number of psychiatric symptoms at age 8 years. Altogether, bully-victims accounted for nearly one third of psychiatric diagnoses made in early adulthood. The findings that bully-victims have the most psychiatric problems is consistent with those showing that children displaying both emotional and behavioral problems are the most unfavorable group regarding psychiatric problems in the long run (64).

A multinational study with data from 25 countries found that adolescent bullies are more likely than others to drink alcohol and to get into fights (36). Alcohol-related problems in late adolescence have also been found to be associated with being a bully at school age by Niemelä and colleagues (65). Kaltiala-Heino et al. (43) found that frequent excessive drinking and the use of other substances was most common among bullies and thereafter among bully-victims. Furthermore, being bullied predicted drunk driving offences in late adolescence (61).

When the future of children with bullying problems is followed up to late adolescence and adulthood, several detrimental outcomes that are known to be related to psychiatric problems and personality disorders have been found. Nansel et al. (50) reported that involvement in bullying, both as bullies and targets, was associated with the greater probability of weapon carrying, fighting, and injury from fighting, and researchers point out that bullying can be considered to be an important marker for more serious violent behaviors. In particular, the risk for violent behaviors was higher if the bullying was experienced away from school surroundings.

Bullying is also associated with future criminality among males (61, 53). Olweus (63) reported that a third of those who were bullies in early primary school had several convictions by the age of 24 years, which is far more than the figure for others. In a study using information about criminal offences from a police register, young males who had been frequent bullies and bully-victims at the age of 8 years were responsible for one third of all juvenile crimes during a 4-year follow-up period at ages 16 to 20 years (61). Bullying also predicted various types of offending: violence, damage to property, drunk driving, and traffic offences. Frequent bully status at age 8 predicted both occasional and repeated offending, and frequent bully-victim status predicted repeated offending. However, only those involved in bullying with a high level of contemporaneous psychiatric symptoms at age 8 years had an increased risk for later criminality.

Our current knowledge about future problems related to bullying is mostly related to males only, whereas the future and developmental pathways of females involved in bullying is far more unclear. According to the current knowledge consequences of bullying, however, might vary according to the gender as several studies suggest various risk profiles for males and females. A follow-up study showed that frequent victimization at age 8 years predicted later suicide attempts and suicides among females (information up to the age of 25 years) even when conduct and depression symptoms at age 8 yrs were taken into account which was not the case among males (66). On the other hand some current studies (having however clearly shorter followup times) have suggested that genders react to bullying in a similar way and for example boys have similar risk for depression as girls (67) and peer victimization at school is equally associated with mental health problems among boys and girls (68).

Both Undheim and Sund (67) as well as Bakker et al. (68) suggest that boys and girls are getting more similar these days so gender per se is unlikely to result in different reactions to the same peer stressor.

BULLYING AS A SIGN OF HEALTH PROBLEMS AND NEED FOR PSYCHIATRIC INTERVENTION

Findings from numerous studies carried out in various countries and cultures have shown an association of psychiatric symptoms, disorders and bullying, and recently this association has been reported to continue after a decade or more. Long-term effects of being bullied in school years on adult personal relationships have also been reported (69-70). Studies have also shown an association of bullying and referral to psychiatric consultation (11, 54), indicating a relationship of bullying and psychiatric problems also in real life. The association between involvement in bullying at early elementary school age and use of the psychiatric services is seen even after a 10-year follow-up (33). The probability of being concurrently referred for a psychiatric consultation is highest among bully-victims, followed by bullies and then by victims (11,54). In a sample of elementary school-aged children, the probability of bully-victims being referred at some time was 5.1-fold that of non-involved children. For bullies, the probability of being referred was slightly lower (4.6-fold) and lower still for victims (2.0-fold). Involvement in bullying even more clearly increased the probability of having been referred for psychiatric consultation in the previous three months (8.7-fold for bullies, 7.1-fold for bully-victims and 2.6-fold for victims) when compared with children not involved in bullying (54).

In a study of medication use among 5,205 adolescents in grades 5, 7 and 9, Due et al. (71) evaluated health problems, medicine use (for headache, stomachache, difficulties in getting to sleep and nervousness), bullying, and various psychosocial conditions, using anonymous reporting. They found that adolescents who are victimized use more medication for pains and psychological problems than do others. The increased risk for medicine use was not explained by the higher prevalence of symptoms among the victims. The researchers point out that not only do bullying behaviors have health-damaging effects in the psychological domain, but also the medications used more frequently by victims might have adverse effects on these children. They call attention to the need for awareness about the excessive use of medicine among victims, and argue that preventive actions should be taken in both areas - to decrease the level of bullying and the use of medicine among adolescents.

CONCLUSIONS

In general we can say that bullying is clearly a highly distressing experience and few single behaviors signal the need for psychiatric evaluation as clearly as bullying does. Many studies have pointed out that teachers, who meet children and adolescents on a daily basis, are in a unique position to detect childhood problems such as bullying behaviors, and to intervene, including arranging referral for psychiatric consultation. Many teachers are aware of bullying problems at school, and various projects and programs against bullying have taken place at many schools. However, bullying has been largely disregarded by child health professionals until now. In the last ten years several papers have addressed the need for pediatricians, general practitioners, school nurses and child mental health professionals to take action when bullying problems emerge, and to consider these problems as possible reasons for the children's somatic or psychiatric symptoms (15,72-74). Even active screening for psychiatric problems among children involved in bullying using parent and teacher symptom checklists has been suggested

(61). Juvonen and colleagues (17) also suggest that in addition to addressing bullying directly with children and their parents pediatricians can also recommend school based antibullying programs that aim to change peer dynamics that support and maintain bullying. Preventive actions should start very early, most preferably at home before the child starts school. Parents and other caregivers should teach children the social skills and the ability to resolve conflicts and to deal with emotions, as Lyznicki and coworkers (73) point out. Research so far suggests that bullying behaviors should be addressed at school (5,8), but there are also studies showing that this is not enough for children who have psychiatric symptoms (19). Bullies, victims and bully-victims with psychiatric symptoms need closer attention and most probably also psychiatric intervention.

ABSTRACT

Being a victim or perpetrator of school bullying, the most common type of school violence, has been frequently associated with a broad spectrum of behavioral, emotional and social problems. Suicide is third leading cause of mortality in children and adolescent in the US and around the world. This chapter provides a systematic review of the previous 37 studies conducted in the children and adolescents from communities as well as in special populations that examined the association between bullying experiences and suicide, with an emphasis on the strengths and limitations of the study designs. Despite methodological and other differences and limitations, it is increasingly clear that any participation in bullying increases the risk of suicidal ideations and/or behaviors in a broad spectrum of youth.

INTRODUCTION

“Bullying” is an aggressive behavior in which individuals in a dominant position intend to cause mental and/or physical suffering to others (1). Bullying is a serious public health problem with the international prevalence ranging from 9-54% (2-4). All participants in bullying are reported to be at substantially increased risk for significant mental and/or physical sequelae of bullying. Victimized children are reported to have a myriad of clinical problems, including bed

^{*} Corresponding Author’s Email: young-shin.kim@yale.edu.

wetting, sleep difficulties, anxiety, depression, school phobia, feelings of insecurity and unhappiness at school; they may also have low self-esteem, loneliness, isolation and somatic symptoms (5-12). In contrast, perpetrators of bullying are reported to have more depression and are more likely than are their peers to be involved with antisocial behaviors and legal problems later in adulthood (10,13). Victim-perpetrators, (aggressive victims) are considered to be a distinct subtype of school bullying, experiencing more psychopathology, as well as problematic family and educational profiles that differ from the other two school bullying subtypes (14).

Suicide, the third leading cause of mortality for adolescents in the US and around the world, is one of the most serious symptoms of psychopathology (15). For example, a recent, large scale, epidemiological study in the US suggested that in the past year, 19% of the high school students had serious suicidal ideation, 15% made a specific plan to attempt suicide, 8.8% reported suicidal attempts and 2.6% made a suicide attempt that was serious enough to require significant medical attention (16). Similarly, a 2001 Korean study found that the rate of completed suicides for adolescents (from 11 to 19 years) was 15.5 per 100,000, making suicide the third leading cause of death, after car accidents and cancer (17). For children at greater risk for suicide, perceived peer rejection, being bullied and being perpetrators of bullying were associated, directly and indirectly, with major depression, substance use and antisocial behavior with severe suicidal ideation (18-20).

The goals of this chapter were: (1) to provide a systematic review of the previous studies that examined the association between bullying experiences and suicide, with an emphasis on the strengths and limitations of the study designs; and (2) to shed light on directions for future research.

IDENTIFICATION OF RELEVANT LITERATURE

A literature search was carried out using six databases, without date specification: Web of Science, SCOPUS, EMBASE, PubMed, PsychInfo and Ovid Medline. The search terminology included: 1) Bullying included either bully*, peer victimization, peer aggression, relational aggression, peer relation, school violence, school aggression, social dominant*, social hierarchy* or peer abuse; AND 2) Suicide included either suicide, suicide attempt, suicide ideation, suicide behavior, self-harm or self-injurious behavior. The subsequent literature search resulted in 867 papers, which was narrowed to 103 relevant papers by further review of abstracts. Among these 103 papers, 37 papers that met our inclusion criteria (below) were finally selected for this review paper.

Studies were included in the review if they met the following criteria: 1) age of study participants is = high school students in general population and all age ranges in special populations, including populations with developmental disorders, behavioral disorders, of homosexual and/or bisexual orientation or at detention centers; 2) statistical methods were described so that the appropriateness of the analyses could be evaluated; 3) quantitative research that provided numerical data regarding bullying/peer victimization exposure and suicidal risks; 4) measures for bullying or peer victimization were described; and, 5) measures of suicidal behaviors, ideations or self-injurious behaviors were described.

Studies were excluded in the review when: 1) no quantitative data were provided; or 2) suicidal risks were not compared between bullying and non-bullying groups.

The studies were grouped according to the characteristics of the study population: 1) children and adolescents of general population; and, 2) special population, including people with Asperger Disorder (AD), Learning Disorders (LD), behavioral disorders, homosexual and/or bisexual orientation or at detention centers. Within each group, suicidal risks were categorized by the types of suicidality: 1) suicidal ideation including suicidal thoughts and suicidal plans; 2) suicidal attempts including suicidal behaviors and self-injurious/self-harm behaviors; and, 3) a composite variable of any suicidality.

Since this chapter aims to provide a systematic review of the previous studies that investigated the association between bullying experience and suicide risks rather than to create a statistical summary of suicidal risks in people with bullying experience, the authors did not perform meta-analysis.

The authors selected odds ratios (ORs) with 95% confidence intervals (CIs) for presenting suicidal risks in the summary tables because: 1) ORs are the most common risk ratios researchers used in their original studies; 2) ORs are conceptually intuitive to understand for most of the readers; and, 3) Suicidal risks represented by ORs can be easily translated into clinical practice for the children and/or their families. In those instances in which when ORs were not available, statistical method and findings that were used in individual research were noted in footnotes.

In the examination of the relationships between bullying and suicidality, adjustments must be made for several confounding factors. These factors include: 1) sex; 2) psychopathology (depression, aggressive-impulsive behaviors and disruptive behaviors); 3) a history of suicide; 4) parental divorce; and, 5) sociodemographic disadvantage. In this review, covariates that were controlled in the analyses to examine the relationships between bullying experience and suicide were examined and listed in the summary tables.

THE NATURE OF THE STUDIES

The search strategy identified a total of 37 studies as eligible for inclusion in this review. Two reports included separate results for either subgroup of study sample (23) or same sample (26,28). These two studies were reviewed separately under the same author list.

Researchers from 16 countries and five continents have conducted research on the bullying and suicide. Approximately a half of these studies were conducted in the US, one third in Europe and the rest were conducted in Australia, South Korea, Japan, South Africa and Canada. Nine out of 17 US studies (53%) used data from the Youth Risk Behavior Survey (YRBS). To monitor priority health-risk behaviors among youth and young adults, Center for Disease Control (CDC) developed the Youth Risk Behavior Surveillance System (YRBSS) (21). YRBSS includes national, state, and local school-based surveys of students in grades 9–12 that have been conducted biennially since 1991. YRBS is a data from these ongoing YRBSS surveys.

Table 1. Summary of the studies selected for the review (total number of studies: 37)

Characteristics of Study Methods	Number	Percentage
Countries of Study Participants		
1. North America (n=18)		
US	17	45.9
Canada	1	2.7
2. Europe (n=13)

Suicide Measure		
1. Self Report	36	97.3
2. Clinical Assessment/Interview	1	2.7
Measures of Suicidality ⁺		
1. Suicidal Ideation	20	54.1
2. Suicidal Behaviors/Self-Harm Behaviors	20	54.1
3. Composite Variable of Suicidality	8	21.6

⁺: Sum of each item is greater than 100% because some studies measured multiple aspects of suicidality including suicidal ideation, attempts and/or self-harm behaviors.

All 37 studies were cross-sectional surveys. 73% of studies were conducted in children and adolescents in their communities; the rest were performed in special populations, such as populations with developmental disorders (AD and LD), drug problems, legal problems and homosexual or bisexual orientations (see table 1.)

MEASUREMENT OF PREDICTORS: BULLYING

92% of research measured bullying using self-report: 5% (two studies) (22, 23) used peer nomination to identify bullying and another 3% (one study) of research interviewed children with Kiddie-Schedule for Affective Disorders and Schizophrenia-Present and Lifetime (K-SADS-PL) (24) to identify bullying experience in the study populations (see table 2.) The time frame of bullying experience inquired ranged from 'ever in the past', 'for the last six months' to 'weekly experience.' The self-reports of bullying can be further divided into three categories:

- Self-reports designed to identify bullying experience with items describing specific bullying behaviors. Items in these self-reports include -
 - Physical bullying such as pushing, shoving, grabbing, kicking, biting or hitting;
 - Verbal bullying such as insulting, threatening, calling names or spreading rumors; and,
 - Exclusion such as being ignored, being rejected, or no talking.

The number of items included in this category of self-reports varies across studies, ranging from one²⁵ to 40 items²⁶. This category is represented by 13 studies (23,25-33).

- Self-reports designed to identify a broader range of behavioral aspects of bullying and the experiences of children and adolescents that resemble bullying behaviors, peer abuse or peer victimization. Examples of this type of self-report of bullying include the use of items from YRBS survey. Included were YRBS survey items -
 - How many days did you not go to school because you felt you would be unsafe at school or on your way to or from school?;
 - How many times has someone threatened or injured you with a weapon such as a gun, knife or club on school property?;
 - How many times has someone stolen or deliberately damaged your property such as your car, clothing or books on school property?;
 - How often they had started a fight;
 - Have you ever threatened to use a weapon to get something from someone; and,
 - Have you ever used a weapon to threaten or assault someone.

Sixteen studies used this type of self-report to identify bullying experience (34-49).

- Self-report designed to identify bullying experience with direct inquiry about 'bullying' experiences with or without the provision of a definition of bullying. The bullying survey in WHO Youth Health Study is an example. In this study, children and adolescents were asked how frequently they had bullied others/been bullied during the current term and whether these actions occurred many times per week, once per week, less frequently, or not at all, after the definition of bullying was provided. Eight studies used this form of bullying self-report (50-57).

The peer nomination method was used in two studies. Kim et al. (22) used Korean-Peer Nomination Inventory to identify four types of victims, and/or perpetrators, using the 17 items. Rigby and Slee (23) also used Peer Rating Measures, using the eight items to identify victims and bullies.

In one study, a direct interview was conducted using one item from K-SADS-PL interview to identify bullying experience in children and adolescents²⁴.

MEASUREMENT OF OUTCOMES: SUICIDE

Self-report and interviews were used to measure suicidality in children and adolescents. Three types of suicidality were measured: suicidal ideation, suicidal behavior including self-harm/self-injurious behaviors and composite variable of any suicidality (see table 2). Self-report of suicidality were measured in following ways:

Suicidal ideation

Suicidal ideations that were measured in the selected studies included: “tired of life/occasional thoughts of suicide,” “for last 6 month, thought about committing suicide,” “I have explicit plans of suicide/preparations for suicide.” The time frame covered for suicidal ideations included: “ever,” “past 12 months,” “past 6 months,” “past 2 months,” “past 2 weeks,” and “current suicidal thoughts.” Suicidal ideations were identified using suicide inquiring questions that were created for the surveys, including the YRBS and the EAT (25-28,31,39,42,43,48,51,54), a part of existing questionnaires or interview scales, including Youth Self-Report (YSR), Beck Depression Inventory, Goldberg Health Questionnaire (22,23,50,53), or suicide specific questionnaires, such as Suicidal Ideation Questionnaire (49,56).

Suicidal behavior

Suicidal Attempts included in this review paper were measured by items such as, “Have you ever on purpose tried to take your own life?” and “Have you attempted suicide in the past 12 months that resulted in an injury requiring medical attention?” Suicidal attempts were identified using suicide inquiry questions that were created for the particular survey, including the YRBS survey (25,31,33,35,37,39,40,43,45-48,51,53), or a part of existing questionnaires or interview scales including YSR, or Diagnostic Interview Schedule for Children (22,56). Self-harm/injurious behaviors were identified by self-harm/injurious behavior questions that were created for the survey (52), or a part of existing interview scales such as K-SADS-PL (57). Items assessing self-harm/injurious behaviors that were identified in the selected papers ranged from “Have you cut your wrist and/or arm more than once?” to “Have you deliberately taken an overdose of medication or tried to harm yourself in some other way?”

Composite score of any suicidality

Eight studies created a single composite score of suicidality based on the responses to the multiple questions on suicidal ideations and/or suicidal behaviors asked of study participants. This composite variable of suicidality became the outcome of interest (29,30,32, 34,36,38,41,44).

Interviews were performed in one study to measure suicidal ideations and behaviors. Mill et al. (24) conducted interview using 19-item Scale for Suicide Ideation to measure current and past suicide ideations, and 19-item Suicide Intent Scale to quantify suicide intent and attempts. One study did not describe how they measured suicidal ideations and attempts (55).

COVARIATES ADJUSTED IN THE ANALYSES TO EXAMINE ASSOCIATIONS BETWEEN BULLYING AND SUICIDE

Covariates that were adjusted in the examination of the association between bullying and suicide were summarized in tables 3 and 4. Among the studies conducted in general populations of children and adolescents, 23 out of 27 studies adjusted for sex whereas 5 out of 10 studies in special populations controlled for sex in the examination of the relationship between bullying and suicide. Eight studies conducted in the general population, as well as four studies of special population, adjusted for other psychopathological risk factors for suicide. These risk factors included depression, substance abuse or emotional/psychological distress.

Only a single study out of the total of 37 studies considered past suicide history as a covariate in their analyses (54). Seven studies using a general population adjusted for parental divorce or family structure as a proxy for parental divorce in their analyses, whereas none of the studies of special populations did so. Additionally, 21 studies of the general population, as well as six studies of special populations, controlled for socioeconomic disadvantages including SES, poverty, exposure to violence, social capital and social support, and demographic information, such as age and race.

SUICIDE RISKS IN CHILDREN AND ADOLESCENTS WITH BULLYING EXPERIENCE

Risks of suicidal ideations, suicidal attempts and composite risks of any suicidality that were associated with bullying experience are summarized in two tables: Table 3 summarized 27 studies in general population of children and adolescents and table 4 summarized 10 studies in special populations.

Shtayermman (2007) ⁴⁹	Cross-sectional (AS)	None	No association		

*: Multiple regression, **:ANOVA, §: Correlation, §§: Frequency (chi-square test), §§§: Fisher's exact test, +: Cohen's D indicator of effect magnitude, ++: Path-analysis, LD: Learning Disorder, LGB: lesbian/gay/bisexual, AS: Asperger Syndrome.

Using fifteen samples from the general population, studies examined the risks of suicidal ideations in the victims of school bullying. While three studies reported no association, 12 studies reported increased risks of suicidal ideations in the victims of bullying, with ORs ranging from 1.4 to 5.6. One study reported a statistically significant interaction with sex: female victims were at a greater risk of suicidal ideations than male victims (22). Additionally, three studies reported dose-response-relationships: frequent victimization was associated with higher risks for suicidal ideations than less frequent victimizations (26,50,56). Eight out of 10 studies that examined the risks of suicidal ideations in the bullying perpetrators from general population, reported increased suicidal risks, with ORs ranging from 1.4 to 9.0. One study (22) reported significantly higher risks of suicidal ideations in female perpetrators than in male perpetrators, and three studies (26,50,56) reported dose-response-relationships for frequency of perpetrating behaviors and suicidal risks. All five studies that examined risks of suicidal ideations in the victim-perpetrators (VPs) of school bullying in general population reported increased risks, with ORs ranging from 1.9 to 10.0. The suicidal risks in VPs were highest among all the groups involved with bullying in four studies (22,53,55,56), and one study reported higher suicidal risk in female VPs compared to male VPs (22).

Thirteen studies examined risks of suicidal attempts, including self-injurious behaviors, in the victims of bullying in general population and 12 studies reported increased risks, with ORs ranging from 1.5 to 5.4. One study reported significant interactions between suicidal risks and female sex (25) and one study showed dose-response-relationships (56). Two studies (53,56), out of the four studies that examined risks of suicidal attempts in the perpetrators of bullying in general population reported increased suicidal risks, with ORs ranging from 2.3 to 9.9. One study also reported dose-response-relationships between perpetrating behaviors and suicidal risks (56). All five studies that examined the composite risks of any suicidality in victims of bullying in general population reported increased risks of suicidality, with ORs ranging from 1.7 to 2.5. Two studies also examined the risks of composite suicidality in perpetrators and reported increased risks with ORs ranging from 1.3-1.4.

Five studies examined risks of suicidal ideations in victims of bullying in special populations and four studies reported increased risks in juvenile offenders, people with LD and lesbian/gay/bisexual (LGB) sexual orientation, with ORs ranging from 1.7 to 2.1. One study that examined the risks of suicidal ideations in perpetrators of bullying among juvenile offenders reported lowered risks compared to the ones not involved with bullying (31).

Seven studies investigated the risks of suicidal attempts and self-injurious behaviors in the victims of bullying in special populations and six reported increased risks, with ORs ranging from 1.4 to 4.6. The special populations with increased suicidal risks included people with LD, drug abuse, juvenile delinquency and of LGB sexual orientation. Also, one study reported the increased risk of suicidal attempts in the perpetrators of the children and adolescents with LD with OR 2.7 (37).

Additionally, one study examined composite risks of any suicidality in the people with LGB sexual orientation and reported that bullying had a mediating role between gender role conformity and suicidal risks (32).

DISCUSSION

Suicidality, the third leading cause of mortality for adolescents, has been examined in relation to bullying in 37 studies conducted in various countries. The majority of these studies reported positive associations between all bullying types and suicidal risks, with strongest risks in Victim-Perpetrators, both in general populations of children and adolescents and populations with special needs (behavioral problems or of LGB sexual orientation.) In addition, a few studies found suicidal risks differed on the basis of sex, as well as with regard to dose-response-relationships. The ORs for suicidal risks associated with bullying experience ranged from 1.4 to 10.0. These prior findings need to be interpreted with caution due to three important, methodological problems:

1. When examining the relationship between bullying and suicidality, most of these studies failed to control for other well-established suicide risk factors, including sex, psychopathology (depression, aggressive-impulsive behaviors and disruptive behaviors), and a history of suicide (58). Twenty eight of the 37 studies controlled for sex. Twelve studies also controlled for psychopathological risk factors for suicide, including depression, substance abuse or emotional/psychological distress. Only a single study controlled for sex, depression and previous suicidal history; this paper reported a negative association between bullying and suicide (54). Taken together, the interpretation of the observed positive associations between bullying and suicide in these studies is seriously limited as uncontrolled risk factors may have confounded the relationships between bullying and suicide.
2. The interpretation of these findings is complicated by shared method variance caused by the use of the same informants to identify both bullying status and suicidal behaviors/ideations (59,60). In those instances, self-reports of bullying are based on the individuals' own perception of the social circumstances, a situation in which it is possible that the psychopathological characteristics of the reporter can lead to misinterpretation of otherwise normal social events. This can result in a confounded relationship between suicide and bullying. Two of the 37 studies used peer nomination to independently identify bullying type and self-reports for delineating suicidal thoughts/behaviors; both of these studies reported increased risk of suicide in students with bullying experience (22, 23).
3. All 37 studies were cross-sectional, making it impossible to make causal inferences or conclusions that experiencing bullying increased suicide risks.

Future studies should address these major methodological limitations in order to establish causal relationships between bullying and risks of suicide. Ideally, future studies should be long-term, prospective in large community samples of children and adolescents, as well as in special populations, and with multiple informants to identify predictors and outcomes. The analyses should be planned and conducted carefully to control for confounding effects of other well-established suicidal risk factors. Findings should be replicated by independent researchers in independent study populations.

In the meantime, this systematic review of 37 previous studies that were conducted in various countries suggests that bullying is a serious problem for our youth and communities. Not only does bullying interfere with normal developmental and educational processes, it also places adolescents at an unnecessary and additional risk for suicidal thoughts and actions. It seems clear that these adolescents are at increased risk for suicidal behaviors/ideations and deserve our particular care and attention. Additionally, inclusion of screening and monitoring of suicidal signs and symptoms in victims, perpetrators or victim-perpetrators in the anti-bullying programs may be an effective way to reduce suicidality in the children and adolescents with bullying experience. Finally, careful clinical evaluation for suicidality in children with bullying experience should be a standard practice that is part of routine primary care visits.

While many adolescents may experience bullying, either as participants or observers, the fact that it is common does not imply that it is “normal” and, hence, an acceptable part of “normal development.” Indeed, evidence from this review, suggests that exposure to bullying, especially for participants, is harmful. Therefore, it is imperative that there now be a common goal to actively intervene to reduce bullying in all communities and to seek out both victims and perpetrators to protect them from suicidality and other potential lethal adverse consequences of this serious public health problem.

Chapter 81

MORBIDITY AMONG BYSTANDERS OF BULLYING BEHAVIOR AT SCHOOL

Ian Rivers*, PhD

School of Sport and Education, Brunel University, UK

ABSTRACT

The role of the bystander is not one that is easily understood in the anti-bullying literature. Roles within the unofficial hierarchy of the schoolyard and playground overlap considerably, and each role has its own social dynamic that brings with it a shifting behavioral landscape that affects every student. In this chapter, the mental health correlates of three categories of bystander are explored: the co-victim, the isolate, and the confederate. Each category of bystander has its own characterizations and mental health correlates. Reports of posttraumatic stress, internalised hostility, substance use, and suicide ideation are discussed with reference to studies involving witnesses of family abuse, community and school violence and well as bullying. It is argued that bystanders are the key to challenging bullying in schools, and their mental health and well-being is pivotal to the effectiveness of anti-bullying interventions.

INTRODUCTION

The role of the bystander is much misunderstood. Social psychologists have long focused upon the bystander as an individual who observes but does not invest (through action) in the situation he or she witnesses. Early research on bystanders, and particularly that addressing bystander apathy, omitted to explore whether or not witnesses were affected by what they had observed. Indeed, it seems that much of this research has inferred that bystanders were left, to all intents and purposes, unscathed by the series of events that unfolded before their eyes. In social-psychological terms, this lack of action has been accounted for by situational ambiguity where cues to the appropriate level of response are taken from observing the activities (or lack thereof) among other bystanders (1). Such is the case of Catherine Susan ('Kitty') Genovese

* Corresponding Author's Email: ian.rivers@brunel.ac.uk.

whose murder in 1964 in the street was supposedly witnessed by no less than 38 neighbours – none of whom were reported to have called the police as they watched this helpless woman being stabbed repeatedly. Popular misreporting of the case and subsequent studies based upon this misreporting suggested that the neighbours' lack of action could be explained in terms of a diffusion of responsibility wherein each observer was only partially responsible for her or his inaction. However, more recent critics of such research have argued that it is necessary to understand the social dynamics at play in instances of bystander apathy, not only taking into account the ambiguities (if indeed there are any), but also the cultural dynamics that underpin the acceptability or justification for certain actions, particularly in cases where men assault women (2,3).

WHAT IS A BYSTANDER?

As noted above, a bystander has traditionally been portrayed as someone who has acted in the role of an observer but has not become involved in that he or she has observed (4). Thus, in violent interactions, such as the Genovese murder, the role of the bystander has not been, unless prompted otherwise, allied to that of the perpetrator or the victim. However this view of the bystander is not one that sits comfortably with those researchers who have observed the violent interactions that occur daily in the yards and playgrounds of our schools. Indeed the school yard view is one more closely allied to that of the critics of those early studies where the social dynamics that underpin the official and unofficial hierarchies in play at any given time determine which students will be subjected to the violent behaviour of others (the '*victims*'), which students will hold the power to enact it (the '*bullies*'), and which students will be, for the present, reprieved to the sidelines (the '*bystanders*'). However, it is the nature of that reprieve which has prompted further research and forms the foundation of this article. How does a student ensure that he or she does not become a future victim? What investment (if any) does he or she make in the social dynamics of the school to ensure his or her personal safety?

Christina Salmivalli and her colleagues in Finland were perhaps the first researchers to explore more closely the social dynamics of the school yard and playground, and to identify four very different types of bystander – *the assistant, reinforcer, defender* and *the outsider* (5). Each of these types of bystander has a very particular role and investment within the unofficial hierarchy. At the top of the schoolyard 'hierarchy' sits the bully with his or her *assistants*, followed by those who reinforce the bully's actions by encouraging him or her, or by laughing at the victim's plight (*the reinforcers*). Next to come are *the outsiders* whose modus operandi is to attempt to keep away from any and all altercations. Following *the outsiders* come *the defenders* - students who support the victim either by trying to stop episodes of bullying or by offering support and friendship to him or her. Although not victims themselves, unless their social status is unassailable within the schoolyard hierarchy, the potential for victimization is an ever present danger for defenders when they intervene. Finally, at the bottom of the hierarchy are the victims whose daily taunts have been the focus of much of bullying literature. By way of contrast, Stuart Twemlow and his colleagues explored the roles of the victim, victimizer, and bystander respectively from a psychodynamic as well as behavioural standpoint (4). They argued that these roles are co-created, defined dialectically and, when individuals occupy these roles, they are 'mentalized' – demonstrating impairment in self-awareness, self-agency, reflexivity, as well as an inability to assess the mental states of others as well as themselves.

They identified seven different types of bystander, each distinguished by the degree to which they act upon the feedback they receive from others and the subjective state associated with the role they take up. The first type of bystander – *the bully bystander* – is excited by the prospect of victimizing others whereas *the puppet-master variant of the bully bystander* manipulates social situations and is committed to violent interactions with peers. *The victim bystander* is fearful, apathetic, and perceives himself or herself to be helpless. *The avoidant bystander*, like *the outsider*, withdraws from bullying episodes and allows them to continue by denying their existence. *The abdicating bystander* refuses to take responsibility for those less able to defend themselves, and considers those victims to be deserving of their lot in life. The *sham bystander* protects himself or herself from victimization by ‘taking on’ the role of victim or victimizer when it is appropriate. Finally *the helpful bystander* is compassionate, horrified by the harm done to others, and develops social skills to resist any potential for victimization for himself or herself as well as for others.

Most recently, Rivers and colleagues have used students’ reports of their own experiences to identify four behavioural categories of bystander – *bully-witness*, *victim-witness*, *witness*, and *bully-victim-witness* (6). Although not as refined as those role descriptors offered by Salmivalli, Twemlow and their colleagues, the measure used (the Olweus Bully/Victim Questionnaire with mirror questions for witnesses) demonstrated that bullying can have an effect upon the whole school population, with the majority of students reporting having witnessed bullying up to a few weeks before they were surveyed.

As table 1 illustrates, comparison between the three studies cited above demonstrates a significant degree of overlap with approximately seven different types of bystander (collapsing Twemlow et al.’s *the bully bystander* and *the puppet master variant of the bully bystander* into one). However, in terms of understanding the potential implications of bystander status for well-being and mental health, it is possible to cluster these roles into three distinct categories: 1) those who are also victims or co-victims (i.e., they experience upset at the sight of others being tormented) – hereafter referred to as *the co-victim*; 2) those who actively avoid bullying situations or deny their existence – *the isolate* and 3) those who actively seek to deflect attention away from themselves by highlighting the inadequacies or failings of others, or by supporting bullies in their endeavours – *the confederate*.

MORBIDITY AMONG BYSTANDERS: ISSUES TO CONSIDER

Given that there are potentially three very different categories of bystander, it also stands to reason that the mental health implications will also vary according to the category or type of bystander a student becomes. Theoretically, it might be expected that those who actively seek to deflect attention onto others and act to support bullies (*the confederate*) may experience remorse or cognitive dissonance much more so than those who, by virtue of their empathy or sensitivity towards the plight of victims and by their abject fear of personal persecution may display many of the psychological symptoms normally found in victims of abuse (*the co-victim*). In the following sections of the article, each of the categories of bystander will be explored further, focusing particularly upon the potential harm to well-being and mental health that may be associated with being a witness to bullying behaviour at school.

Table 1. Bystander roles

No. of bystander types	Individual & behavioural characteristics		
	Salmivalli et al. (1996)	Twemlow et al. (2004)	Rivers et al. (2010)
Type #1	<i>Assistant</i> Passive followers, joined in harassment when started by others.	<i>Bully bystander</i> Sets up opportunities for victimization of others <i>Puppet-master variant of Bully bystander</i> Seeks violent outcomes through manipulation of others.	<i>Bully-witness</i> Sometimes a bully and sometimes an observer.
Type #2	<i>Reinforcer</i> Provide bullies with positive reinforcement of behaviour	<i>Abdicating bystander</i> Scapegoats others	
Type #3	<i>Defender</i> Provides support to victim in or after bullying episodes, actively tries to stop bullying	<i>Helpful bystander</i> Mature use of individual and group psychology to stop bullying episodes, skilled in resisting victimization	
Type #4		<i>Victim bystander</i> Passive, drawn into the victimization process by fear	<i>Victim-witness</i> Sometimes a victim and sometimes an observer
Type #5	<i>Outsider</i> Withdraw from bullying Situations	<i>Avoidant bystander</i> Denial of personal responsibility	<i>Witness</i> Observes bullying but has not been a victim or bully
Type #6		<i>Sham bystander</i> Role of victim or bully is adopted for personal political reasons.	
Type #7			<i>Bully-victim-witness</i> Takes on multiple roles at school; sometimes a bully, sometimes a victim, other times an observer

Table 2. Symptoms responses of students exposed to community/school violence by grade/age (Adapted from Pynoos & Nader, 1988)

Preschool-2 nd Grade (4-8 Years)	3 rd -5 th Grade (8-12 years)	6 th Grade and Up (12 years +)
Helplessness, passivity	Preoccupation with issues of responsibility and guilt	Detachment, shame, guilt
Generalized fear	Fears related to being alone	Self-consciousness about their own fears, vulnerabilities, fear of being labelled different
Cognitive confusion	Traumatic play (retelling and replaying an event)	Post-traumatic 'acting out', drug use, anti-social behaviour, inappropriate sexual behaviour
Difficulty in identifying source of worry	Fear of being overwhelmed by feelings (e.g. crying, anger)	Self-destructive/accident prone behaviour
Selective mutism, nonverbal traumatic play	Impaired concentration/learning	Difficulties in interpersonal relationships
Attributing 'magical' qualities to reminders of trauma	Sleep disturbances	Focus on revenge/retribution
Sleep disturbances	Concerns about safety of self and others	Significant changes in attitudes towards life
Anxious attachment (clingy behaviour, concern at caregiver's absence)	Inconsistent/unusual/out of character behaviour	Leaves school early, marries/embarks upon a relationship early, reluctant to leave home
Regressive behaviour (thumb sucking, bed-wetting, regressive speech patterns)	Somatic complaints	
Anxieties related to failure to understand concepts such as death	Concerns about impact on parents, others	
	Disturbed/ frightened by their own grief	

The observations made are informed by various studies conducted by researchers and clinicians who have worked with individuals and families who have experienced or witnessed various forms of trauma and abuse.

The co-victim

Within psychiatry it is well understood that an individual can be traumatized by the very act of observing someone else losing his or her life, or by the potential threat of personal injury or death in the face of a natural disaster (eg. earthquake or tsunami) or man-made event (eg. road traffic accident or act of terrorism) (7-9). Researchers have also shown that, in instances where an individual - particularly a young person - has taken his or her own life, there is often a need to provide counselling or guidance to those peers who knew or might empathise with the victim in order to reduce the collective distress caused by such a suicide, or to stem the potential for further loss of life (10).

For the *co-victim* who is affected by the bullying he or she witnesses, clinical research has shown that the potential for long-term psychological harm is as real as if he or she had been the subject of the bully's taunts. For example, in one systematic review of 26 studies of the implications of exposure to community violence among urban adolescents, such exposure was found to be correlated with increased reporting of mental health symptoms, posttraumatic stress, and aggression (11). In one study of 349 youth aged between 9 and 15 years resident in one of ten low-income housing communities, witnessing violence was found to be correlated with reports of distress that included intrusive thoughts and feelings (indicative of posttraumatic stress), difficulties in concentration, and constant vigilant/avoidant behaviour (12). Of particular note in this study was the fact that younger participants as well as boys and those young people who showed an aptitude for problem solving were more likely to report experiencing intrusive thoughts when compared to the other youth in the study. Evidence of emotional numbing, distraction, family problems and a lack of belonging were also found.

The significance of symptoms usually associated with posttraumatic stress disorder (PTSD) among witnesses is well documented, especially in cases where children have observed domestic violence. In one study of 84 children (mean age 11 years) who had been referred from shelters for women abused by their partners, 47 children were found to meet the criteria for PTSD (re-experiencing events, avoidance, and hyperarousal) (13). Furthermore, in a study of symptoms of posttraumatic stress among former victims of homophobic bullying, 26% of participants said that they continued to be distressed regularly by recollections of bullying with 21% reporting distressing or intrusive memories of those events (14). While only 4% said they experienced nightmares about being bullied at school, 9% said they had experienced flashbacks (hallucinations or dissociative episodes), or the feeling that they were reliving the events even though they were awake. In their study of witnesses of bullying behaviour, Rivers and colleagues found evidence of an impact upon psychological functioning among students who had only observed bullying at school and did not report either having been victimized themselves or having victimized others (9). In terms of substance abuse, this study also found that witnesses shared some of the abusive characteristics usually found among perpetrators of bullying suggesting that, for some students, alcohol and drugs were used as a coping mechanism either to escape fear or to alleviate cognitive dissonance. Finally, in a related study, members of the same research team found that witnesses of bullying, particularly those who

were also sometimes victims and sometime bullies, were more likely to report thinking about ending their own lives when compared to those students who were primarily identified as bullies or victims (15).

Although the impact of exposure to violence and fears of recurrence have been researched particularly thoroughly at the community level, including among school-aged children, in a review of research and potential 'first aid' interventions for young people exposed to violence at school, it has been suggested that mental health professionals have a particular role to play in supporting school faculty and staff. On visiting such a school they need to be able to help the teachers build a secure and less anxious classroom environment where students are given permission to express feelings, clarify cognitive confusions, and where they are encouraged to seek help or advice (16). In such an environment it has been argued that young people who are vulnerable and require one-to-one consultations can be easily identified by their symptom responses (see table 2).

While the responses identified in table 2 suggest that they relate to victims rather than bystanders, as previously stated, those who witness violence and are themselves fearful of becoming victims, will also display many of the same symptoms (17). Thus, a whole school or community-wide initiative is often needed to combat trauma resulting from violence.

The isolate

In contrast to the co-victim, there is little specific research on the student who opts to remove himself or herself from bullying situations. In some of the studies that have been conducted to date, these students are often represented as reference groups or control groups, because they report little or no interaction in episodes of school bullying. However, there are significant differences between those students who opt to absent themselves from bullying situations and those who have not seen bullying take place. Methodologically, this suggests that there may be a flaw in the approach some researchers have taken in identifying reference or control groups as professionals working with young people in schools have suggested that those who isolate themselves from others as a means of self preservation can themselves experience mental health difficulties as a result of their isolation (18). Indeed, in the case of bullying in schools, it has been argued that regardless of whether a bystander is passive or provocative, he or she promotes an environment that encourages bullying by failing to challenge it or stand up for the victim (19). Indeed the fear of humiliation and abuse actively encourages some young people to isolate themselves in order to ensure their safety, but comparable with the co-victim, such an approach can itself have devastating effects (20). For example, suicide and para-suicidal behaviour have been associated with reports of extreme social isolation among young people (21). Additionally, while social isolation may, in the short-term, reduce cognitive dissonance and personal responsibility for the welfare of victims of bullying, the desire to intervene coupled with a failure to act can result in internalised hostility and self-loathing which, in turn, may be one of the factors that promotes suicidal thoughts (6) (15). Finally, isolation itself may not be a useful long-term strategy to protect oneself from bullying. Social isolation has been linked to unpopularity among peers, and may actually identify the isolate as a potential victim without popular friends to protect him or her in the face of hostile others (22).

Ultimately there is a great deal more research needed on this particular category of bystander to understand fully the implications of withdrawing from bullying situations, not only in terms of its impact upon school-wide anti-bullying interventions, but also in terms of the mental health of those who choose to isolate themselves as a protective measure.

The confederate

The confederate is perhaps the most conflicted of categories of bystander. As noted previously, this not only includes those who might be identified as *assistants* or *reinforcers*, it also includes those who stand on the sidelines watching bullying take place. As Hazler and Denham pointed out, whether bystanders are proactive or passive in terms of their support for the bully, their actions promote an environment that allows bullying to thrive (19). This particular group are perhaps the most likely to experience cognitive dissonance in that while they attempt to protect themselves they are also likely to be aware of the fact that they are promoting the bullying of others. Research conducted both in the United Kingdom and in Canada suggests that experiences of cognitive dissonance may be directly related to symptoms of internalised hostility, and that self-loathing coupled with anger may result in potentially harmful outcomes not only for the bystander, but also for the victim who may become the object of that anger either through a process of transference or through a desire (by the bystander) to maintain his or her own positive self-image (perhaps as a result of academic failure or difficulties at home) (4) (6) (20) (22). Linked to the above, it has also been found that being both a witness and perpetrator of bullying (*the bully-witness*) predicts elevated levels of substance use - alcohol, tobacco, and class 1 or 2 (US) or A (UK) drugs (6). It has already been argued that substance use may be linked to a desire to dull or escape the effects of cognitive dissonance. In terms of suicide ideation and para-suicidal behaviour, researchers have also shown that this particular group are at greater risk of reporting thoughts of ending life (15). Those who identified as having been victims, bullies, and also witnesses were significantly more likely to contemplate ending their lives when compared to students not involved in bullying interactions, those who were both victims and bullies, those who were both victims and witnesses, and those who were bullies and witnesses. While this particular group (*the bully-victim-witness*) exemplify the type of student who deliberately seeks to protect himself or herself from bullying through an alliance with the bully, it should be noted that this student has never been drawn to the attention of mental health professionals working in schools. However, Twemlow and colleagues have characterized the more provocative bystander as one that is not only thrilled and excited by the prospect of violence being perpetrated against others, but also one that revels in the power he or she holds over the well-being of the victim (4). While it has been argued that among bystanders such characterizations or subjective states demonstrate a cognitive and emotional impairment, other researchers have argued that rather than failing to understand the plight of the victim, bullies and their confederates understand all too well the impact their behaviour has (23). The *sham bystander* is a case in point; he or she consciously manipulates social relationships in a calm and deliberate manner for his or her own political ends.

There is substantially less research on bullies and their confederates than there is on victims, and even less of the mental health correlates of perpetrating or encouraging bullying

behaviour at school. It is important that we understand the ramifications of bystander status in all its guises for the well-being and mental health of our student populations.

DISCUSSION

School bullying is a complex phenomenon that cannot be understood in terms of a simple dyadic relationship between the perpetrator and his or her victim. Roles overlap considerably, and each role has its own social dynamic that brings with it a shifting behavioural landscape that affects every member of a school's student community. While a great deal of research attention has been focused on the mental health correlates of victim status it is clear from this review that much more attention should be placed upon the mental health correlates of bystander status. Whether a student is a passive or provocative bystander, and isolate or a co-victim, he or she is also likely to be suffering. It is incumbent upon schools and those who administer schools to find ways of supporting the whole educational community rather than focusing their attention upon victims and perpetrators. Posttraumatic stress, internalized hostility, substance use, and suicide ideation are issues as commonly found among witnesses as they are among victims of assault, abuse, natural disasters, or man-made events. It should not be surprising to clinicians that those symptoms usually reported among adult populations who have suffered abuse or trauma are also to be found among student populations similarly abused or traumatized as a result of adult or peer violence. However, it seems that there has been some reticence on the part of school and educational authorities to recognize the implications bullying has for the mental health of all the students in their care. Indeed most recently anti-bullying campaigns such as *'It Gets Better'*, while highlighting the significant mental health implications of bullying (homophobic bullying in this instance), take the focus away from 'the here and now' and the protection of young people in schools by inferring that the hardships they face today will not affect them in the future. Is it right that we ask young people to wait until they are grown up our school communities are at risk now?

Bystanders have a significant role to play in stopping bullying behaviour. It is important that we find a means of ensuring that bystanders invest in their school environment and make an investment in the welfare of their peers. Twemlow and his colleagues provided a very useful clinical characterization of a pathological and a healthy charisma associated with altruistic helpfulness (this was first developed by Peter Olsson, M.D.). In this characterization the healthy, altruistic individual is one who encourages his or her peers, is empathetic and understanding, is creative, has facilitative skills that support group cohesion, gains reward from helping others, and mentors future leaders in younger classes or grades. It seems likely that if such individuals were to be nurtured through a series of positive programs, it would be difficult for bullies and their confederates to gain power over others at school (4) (24).

This short review provides an outline of the issues that should concern teachers, administrators, school counsellors and psychologists, pediatricians, child and family therapists who work with students involved in bullying. It identifies three categories of bystander, each with its own series of mental health concerns. It is only by understanding the experiences of all of the inhabitants of a school where bullying takes place that it is possible to challenge this pernicious and, alas, still ever present form of abuse.

Chapter 82

PUBLIC HEALTH, SAFETY AND EDUCATIONAL RISKS ASSOCIATED WITH BULLYING BEHAVIORS IN AMERICAN ADOLESCENTS

Jorge Srabstein*, MD and Thomas Piazza, PhD

Department of Psychiatry and Behavioral Sciences, Children's National Medical Center,
Washington, DC and Survey Research Center, University of California, Berkeley, US

ABSTRACT

Based on a national representative sample of middle and high school US students we will in this chapter study the association between different health, safety and educational risk factors and involvement in a variety of bullying behaviors. Based on an analysis of US data of the 1996 World Health Organization Health Behavior in School-aged Children survey with cross-sectional survey information on 9,938 students in grade 6 through 10. Thirty-nine per cent of the students were involved in bullying others and/or were victims of bullies at least three times in the previous twelve months. Bullies, victims, and those who are both, are at a significantly higher risk of suffering from self-inflicted, accidental, and perpetrated injuries, abusing over the counter medications, hurting animals and people on purpose, using a weapon that could seriously hurt someone, and being frequently absent from school, as compared to their peers who are not involved in bullying or rarely participated in it. Those students who are both bullies and victims experience a wide array of associated risk behaviors with odd ratios stretching from 1.54 to 14.17. It was confirmed that participation in bullying behaviors, as a bully or as a victim, is associated with multiple health, safety, and educational hazards. Students who are bullies and/or victims are at a high risk of dying from self-inflicted, accidental, or perpetrated injuries.

INTRODUCTION

An extensive number of studies, published in the past twelve years, have provided evidence indicating that adolescents, who participate in bullying behaviors, are very vulnerable to health, safety and educational risks (1-37). These reports have shown that both victims and/or perpetrators of bullying are significantly more likely than their peers, who are not involved in bullying, in suffering from an array of physical and emotional problems. This includes psychosomatic symptoms (8,11,15,18,19,28,35-37); sadness and/or depression (1,3,23,25,28,29,33,34); anxiety (3,17,33); difficulties in attention, impulsivity and/or hyperactivity regulation (6,36); delusions and hallucinations(16); overweight (26); bulimia (12); smoking (11,13,22) and alcohol/drug abuse (3,9,11,22,24,27). Victims of bullying have been shown to be at a higher risk for truancy and lower academic grades (1,2), but above all participation in bullying, as a victim and/or as a perpetrator, is significantly linked to potential death, due to suicidal ideation or attempts (10,21,29), injuries (20,31), physical aggression and fighting (5,14,27), as well as carrying and using weapons (24,30).

Only four of these studies (2,3,13,32) have been based on longitudinal assessments, while the vast majority of them were results of cross sectional research, frequently supported by student health surveys, administered by the World Health Organization, and based on national representative samples of adolescents (2,5,7-9,11,15,18,20,22-24,26,27,30,31). Their results document a significant link between bullying and an array of different risk factors which may be covariates.

The purpose of our study was to examine, based on a national representative sample of middle and high school US students, the association between different health, safety, and educational risk factors and involvement in a variety of bullying behaviors, both as bullies and/or victims.

THE DATA WE USED

We utilized the data on US students in grades 6 through 10 that appeared in the WHO's Health Behavior in School-aged Children (HBSC) survey for 1996. The HBSC is a nationally representative, school-based study of health-related attitudes and behaviors of adolescents (38,39). The 1996 HBSC survey contained 209 variables, including items about being bullied and bullying, episodes of depression in the previous year, physical and emotional symptoms in the past six months, self-inflicted injuries, accidental or perpetrated injuries, runaway episodes, alcohol and drug abuse, daily smoking, carrying weapons, school absenteeism and poor academic grades (38). This study was considered exempt from Institutional Review Board approval because the database is available in the public domain (40).

"The collection of the 1996 HBSC data was based on a three-stage sample strategy. The school district was the primary sampling unit, the school was the second stage, and the classroom was the third stage. The targeted means in the age groups were 11.5, 13.5, and 15.5 years. The three selected age groups correspond approximately to grades 6, 8, and 10 in the United States. The total number of valid cases was 9,938. To protect the anonymity of respondents, all variables that could be used to identify individuals have been collapsed or recoded in the public use files" (38).

The demographic characteristics included in the analysis were gender, school grade and race. (See table 1). Parental education was not included due to the large proportion of cases with missing data on that set of variables.

Table 1. Demographic characteristics of students involved in bullying behaviors, health behavior in school-aged children, WHO 1996*

	N (unweighted)	None or seldom bullying % **	Bullies only % **	Victims only % **	Both bullies and victims (%) **
Total Sample, N (unweighted)	9574	5830	1372	1164	1208
Sex					
Male	4749	41.3	60.0	45.4	55.9

6th	3173	33.9	24.8	42.1	32.9
8th	3331	31.5	40.1	34.7	37.7
10th	3369	34.6	35.0	23.2	28.8

* All frequencies with a chi-square p-value of less than 0.05 are represented in bold.

** All percentages (%) are column percentage of each bullying behavior category.

Bullying behaviors (see table 2) were defined as being a bully, a victim of a bully, or both a bully and a victim. The students who participated in the 1996 HBSC survey were asked how many times, during the previous 12 months, they were “picked on, ganged up on, or bullied,” “away from school property” and/or “on school property.” They were also asked whether they were involved, in the previous 12 months, in picking on, ganging up on, or bullying other students, outside and/or inside school property (38). Each of these four questions has eight possible answers, ranging from “0 times in 12 months” to “several times a week.”

In our study we defined as participants in bullying behavior those students who were themselves bullied by others (victims) and/or who bullied others, at least three times or more frequently, in school or out of school, during the previous 12 months. The variable “infrequent or no bullying” represents both those students who stated that they were bullied and/or had bullied others only once or twice during the previous year, and also those students who did not participate in any bullying episodes at all.

Table 2. Health, safety and educational risks in relation to bullying behaviors. Health behavior in school-aged children, WHO 1996 *

Health, safety and educational risks	Total N of subjects N= 9574	None or seldom bullying % (SE) N=5830 N=13016	Bullies only % (SE) N=1372	Victims only % (SE) N=1164	Both bullies and victims % (SE) N=1208

* All frequencies with a chi-square p-value of less than 0.05 are represented in bold.

** All percentages (%) are column percentage of each Bullying Behavior category.

Health and safety risk factors (See table 2)

We analyzed the following endpoints which represent a risk to health and safety of self and others:

- Self-inflicted injuries: Trying to injure one-self, on purpose, in the previous 12 months.
- Accidental or perpetrated injuries: Having been hurt or injured, in the previous 12 months, requiring them to stay home from school, see a doctor or nurse, or cut back on other usual activities.
- Injury Requiring Hospital Stay: Suffered an injury requiring overnight hospital stay.
- Alcohol abuse: Having “five or more drinks of alcohol in a row, that is, within a couple of hours,” on one or more days, during the previous thirty days.
- Daily smoking: Smoked one or more cigarettes daily, over the previous 30 days.
- Use of drugs: Use of cocaine, including crack, LSD, PCP, ecstasy,

- mushrooms, speed, ice, or heroin, in the previous 12 months.
- Over-the-counter medication abuse: Having taken an over-the-counter medicine to get high or just to see what it felt like, one or more times.
- Runaway: Having been away from home without the parent's or guardian's permission for at least one entire night, 6 or more times in the previous 12 months.
- Hurting animals: Physically hurting animals on purpose, in the previous 12 months.
- Hurting people: Physically hurting someone on purpose, in the previous 12 months.
- Fire setting: Has set fires, to damage something of value, in the previous 12 months.
- Carried a weapon to school: Has carried a weapon such as a gun, knife, or club, on school property, one or more times, in the previous 30 days.
- Weapon use: Has used a weapon that could seriously hurt someone, in the previous 12 months.
-
-

Educational risks (See table 2)

The following variables were analyzed to ascertain a risk to the adolescent's academic work and performance:

- Absenteeism: Being absent from school, for any reason, 11 or more days, in the previous 30 days.
- Poor grades: Averaging mostly D's and F's
- Skipping classes: Cutting or skipping classes without permission, in the previous 12 months.

The data were analyzed utilizing the Data Analysis System (DAS) of the Inter-University Consortium for Political and Social Research at the University of Michigan. This is an online analysis system that allows users to run both simple and complex analyses, recode and compute new variables, and subset variables or cases for downloading. The software powering the system, the Survey Documentation and Analysis (SDA) system, was developed and is supported by the Computer-assisted Survey Methods Program (CSM) at the University of California, Berkeley (41, 42).

We analyzed the frequency distributions to determine the demographic characteristics of students participating in bullying behavior and the frequency of the health, safety and educational risks in relation to involvement in bullying behaviors. Logistic regression analysis was conducted using the SDA Logit/Probit Regression Program, to examine associations between bullying behaviors and the health, safety and educational risks. Each multivariate logistic regression included gender, grade, and race. Adjusted odds ratios (OR) and standard errors were calculated.

FINDINGS

Thirty-nine per cent (3,744) of students responding to the 1996 United States Health Behavior in School-aged Children survey reported being involved in bullying, at least twice or more, over the previous 12 months, either as bullies or as victims, or as both bullies and victims (see table 1). There was a significantly higher proportion of males participating in bullying as bullies and bully/victims (both bullies and victims).

Non-Hispanic Whites were more likely than average to be involved as victims, while Non-Hispanic Blacks were less prone to be victims and bully/victims. Students of Non-Hispanic Asian or Pacific Islander ethnicity were less likely to be bullies or victims, while Non-Hispanic Native Americans were more likely to be bully/victims.

Frequency of victimization is gradually reduced from 6th to 10th grade. However, those who are engaged in bullying others seem to be more prevalent in the 8th grade.

Table 2 shows a general tendency for almost all the types of health, safety and educational problems to be increased in those adolescents who participate in bullying whether as bullies, or as both bullies and victims. An exception to this pattern is found in the occurrence of daily smoking among bully/victims.

Table 3. Adjusted OR (SE)* for health, safety and educational risks by bullying behaviors, health behavior in school-aged children, WHO 1996

Health, safety and educational risks	Bullies only ***	Victims only***	Bully/victims***
Self –inflicted Injuries**	3.98(1.09)	2.11(1.11)	7.07(1.11)

* Each multivariable logistic regression has, gender, race and grade in the model.

** Row reference group is students who do not exhibit the respective health, safety or educational risk.

*** Column reference group is students who are seldom involved (once or twice per year) or are not involved in bullying, as bullies and/or as victims.

Table 3 shows much the same pattern expressed as the adjusted odds ratios of health, educational and safety problems in the groups participating in bullying to those who are not or almost not involved in this type of behavior. Consistent with the results from Table 2, the odds ratios tend to increase mildly from 0.83 to 2.11 among victims, and moderately from 1.45 to 5.40 among bullies. Those students who are both bullies and victims are affected by a substantial increment in the odds ratios from 1.54 to 14.17.

Bullies, victims, and those who are both, are at higher risk of suffering from self-inflicted, accidental, and perpetrated injuries, abusing over the counter medications, hurting animals and people on purpose, using a weapon that could seriously hurt someone, and being frequently absent from school, as compared to their peers who were not involved in bullying or rarely participated in it.

Students who bully others and those who are both bullies and victims are at significantly higher risk than their cohort not involved in bullying, in experiencing the whole range of health, safety, and educational hazards. Overall, bullies are prone to have their highest risk in use of drugs and setting fires, victims in inflicting self injuries, while those who are both bullies and victims have the maximum degree of peril in carrying weapons to school and setting fires.

DISCUSSION

This is the first study based on a national representative sample of US adolescents to document that students who participate in bullying, whether as bullies, victims, or both, are at a significantly higher risk of suffering from injuries that are self-inflicted, accidental, or perpetrated by others, as compared to their peers who do not participate or who are minimally involved in bullying. This circumstance identifies them as being at peril of dying of any of the three main causes of mortality among young people such as suicide, homicide, or accidents (43). Furthermore, they share a significant risk of abusing over-the-counter medications, hurting animals or people on purpose, using a weapon that could seriously hurt someone, and being frequently absent from school.

Students who bully others, and those who are both bullies and victims, suffer from a higher risk and a broader spectrum of health, safety, and educational risks than those who are only victims of bullying. This range of hazards includes injuries that require overnight hospital stay, alcohol abuse, daily smoking, drug use, runaway episodes, setting fires to damage something of value, carrying weapons to school, having poor grades, and skipping classes. Their mortality risk, due to all type of injuries, could be exacerbated by runaway episodes (44); alcohol abuse (45,46); over-the-counter medication and illicit drug abuse (47,48).

Our study showed similar observations to those made by previous reports (8,21), that among students who are involved in bullying, those who are both bullies and victims suffered from the highest prevalence of morbidity. It also extends the notion supported by Siziya et al. (51) that being bullied is positively associated with truancy, by showing that that same educational risk is linked to bullies and those who are both bullies and victims. Furthermore it sustains previous findings documenting the high risk for bullies and bully/victims of carrying weapons to school (24), smoking (49), and using alcohol and drugs (24,50).

The cross-sectional aspect of the sample utilized, does not allow us to reach any conclusion about the causality in the association between bullying and health, safety, and educational risks.

Nevertheless, it gives us an opportunity to ascertain the degree of association between bullying behaviors and significant public health hazards, as well as a national prevalence estimate of these risks associated with participation in bullying.

We utilized the 1996 USA Health Behavior in School-aged Children (HBSC) as a source for our analysis, because it included questions pertaining to self-inflicted injuries. Unfortunately, this item has not been included in more recent HBSC versions (51,52), or in a similar cross-national research study, namely, the World Health Organization Global School-based Student Health Survey (53,54), which includes questions about bullying, but not about suicide attempts. Furthermore the United States Youth Risk Behavior Surveillance System (55), designed to ascertain the prevalence of risk behaviors, includes questions about suicide, injuries, and school violence, but not specifically about bullying.

These health risk surveys could contribute to the urgent public health need to ascertain the international prevalence trends of bullying in relation to the main causes of youth mortality, if they were to include the necessary variables.

The recognition, on a national basis, of the significant array of life threatening risks and educational problems associated with bullying behaviors should urgently alert pediatric practitioners and educators to the need for joining efforts in the prevention of this very serious public health issue. Such an initiative would be in accordance with the long tradition of the medical profession to create partnerships with the schools for the preservation of the physical and mental health of young people.

Chapter 83

IS THERE A SYNDROME OF BULLYING?

Jorge Srabstein^{1,*}, MD and Thomas Piazza², PhD

ABSTRACT

In this chapter we investigated the existence of a psychosomatic disorder associated with bullying, by delineating its health and safety and correlates, and defining the demographic characteristics of the US adolescents affected by this condition. We based our study on an analysis of US data from the 1996 World Health Organization Health Behavior in School-aged Children survey. The survey provides nationally representative, cross-sectional survey information on 9938 US students in grades 6 through 10. We examined those students who were involved in bullying as a victim and/or as a bully with or without a self-reported cluster of depression, "bad mood", "feeling low", "feeling nervous", and sleeping difficulties, and one or more physical symptoms (headaches, stomach aches, back aches, dizziness). A cluster of physical and emotional symptoms linked to their participation in bullying as bullies and or victims was reported by nine and half percent of adolescents, with a higher frequency of 8th grade students and a predominance of females. These students were 8.14 times more likely to hurt themselves on purpose and 4.20 times more likely to hurt others purposely, than their peers who were not involved in bullying and did not suffer from a cluster of physical and emotional symptoms. This study may elicit further examination and debate about the existence of a nosological entity linked to bullying. Pending further research, the present results should support the need to ascertain participation in bullying, as a bully and/or as a victim, in all pediatric visits. Furthermore there is a need to inquire about symptoms and risks related to this form of abuse.

INTRODUCTION

The association of health problems with participation in bullying has been highlighted for the past several years (1-23). The concept of bullying entails a form of maltreatment manifested by the repeated exposure of a person to either physical aggression by one or more people; and/or being hurt with teasing, name calling, mockery, threats, harassment, taunting, social exclusion or rumors (24, 25).

There is growing evidence that adolescents who bully others and/or are being bullied, are at a significantly higher risk of suffering from an array of health, safety and educational hazards, as compared to their peers who are not involved in bullying behaviors. These hazards include psychotic symptoms (1,9); substance abuse (2); suicidal attempts (6,7,10,15); eating disorders (12); runaway episodes (11); significant absenteeism (11); and injuries which can be self-perpetrated, accidental or caused by others (11,22,23). There is also data supporting a link of bullying to the frequent occurrence of one or more frequently occurring symptoms, such as headaches, stomach aches, dizziness, back aches, depression, irritability, anxiety and sleeping difficulties (3-5,8,17,18,20,21). The occurrence of a spectrum of physical and emotional morbidity, affecting adolescents who bully others and/or are victims of bullying has been previously pointed out (17,20) and is increasingly being detected in our clinical practice.

In this chapter we want to investigate the existence of a psychosomatic disorder associated with bullying, by delineating its health and safety correlates, and defining the demographic characteristics of the US adolescents affected by this condition.

DATA WE USED

We utilized the data on United States students in grades 6 through 10 that appeared in the WHO's Health Behavior in School-aged Children (HBSC) survey for 1996. The HBSC is a nationally representative, school-based study of health-related attitudes and behaviors of adolescents (26,27). The 1996 HBSC survey contained 209 variables, including items about being bullied and bullying, episodes of depression in the previous year, physical and emotional symptoms in the past six months, self-inflicted injuries, runaway episodes, alcohol and drug abuse, daily smoking and carrying or using weapons (26). The 1996 US version of HBSC was chosen, because it includes a question about self-inflicted injuries, which was not repeated in later surveys.

This study was considered exempt from Institutional Review Board approval because the database is available in the public domain (28).

According to the survey documentation, "The collection of the 1996 HBSC data was based on a three-stage sample strategy. The school district was the primary sampling unit, the school was the second stage, and the classroom was the third stage. The targeted means in the age groups were 11.5, 13.5, and 15.5 years. The three selected age groups correspond approximately to grades 6, 8, and 10 in the United States. The total number of valid cases was 9,938. To protect the anonymity of respondents, all variables that could be used to identify individuals have been collapsed or recoded in the public use files" (26).

The demographic characteristics included in the analysis were gender, race, and school grade (see table 1). Parental education was not included because of the large proportion of cases with missing data on that set of variables.

Bullying behaviors were defined as being a bully, a victim of a bully, or both a bully and a victim. The students who participated in the 1996 HBSC survey were asked how many times, during the previous 12 months, they were “picked on, ganged up on, or bullied,” “away from school property” and/or “on school property.” They were also asked whether they were involved, in the previous 12 months, in picking on, ganging up on, or bullying other students, outside and/or inside school property (26). Each of these four questions has eight possible answers, ranging from “0 times in 12 months” to “several times a week.”

Table 1. Demographic characteristics of students involved in bullying behaviors who also suffered physical and emotional symptoms

Demographic characteristics	Total N (unweighted)	Students who are bullies and/or victims and have symptoms	Students who have symptoms and are not involved in bullying	Students who are bullies and/or victims and do not have symptoms	Students who are not involved in bullying and do not have symptoms
	N=9574	N=876	N=715	N=2868	N=5115
Male	4263	38.2%	25.2%	62.6%	43.4%
Female	4827	61.8%	74.8%	37.4%	56.6%
NH White	4233	53.0%	42.2%	52.8%	46.8%
NH Afro-American	1114	7.8%	12.9%	13.4%	14.2%
Hispanic	2328	29.0%	32.3%	25.1%	28.0%
NH Asian-Pacific	757	7.9%	10.6%	7.1%	9.7%
NH Native American	120	2.3%	1.9%	1.6%	1.3%
Grade 6	2806	25.0%	15.5%	34.6%	33.0%
Grade 8	3080	40.9%	32.8%	37.4%	31.1%
Grade 10	3156	33.8%	51.7%	27.8%	35.8%

¹All frequencies with a chi-square p-value < .05 are represented in bold.

²All percentages are column percentage of each bullying and symptoms category.

Data: Health Behavior in School-aged Children, WHO 1996.

In our study we defined as participants in bullying behavior those students who were themselves bullied by others (victims) and/or who bullied others, at least three times or more frequently, in school or out of school, during the previous 12 months. The variable “infrequent or no bullying” represents both those students who stated that they were bullied and/or had bullied others only once or twice during the previous year, and also those students who did not participate in any bullying episodes at all.

PARTICIPANTS IN BULLYING WITH CLUSTER OF PHYSICAL AND EMOTIONAL SYMPTOMS

We identified all those students who were participants in bullying behaviors and who also experienced a cluster of symptoms including: having felt sad, blue, down, or depressed almost every day for two weeks in a row in the previous 12 months; having experienced in the previous 6 months, at least once a week: “bad mood”, “feeling nervous”, “having difficulties going to sleep;” and one or more of the following physical symptoms (headaches, stomach aches, back aches and/or dizziness). They were compared to their peers who: a) participated in bullying but did not experience a cluster of physical and emotional symptoms; b) experienced a cluster of symptoms but did not participate in bullying and c) did not participate in bullying and did not experience a cluster of physical and emotional symptoms.

HEALTH AND SAFETY RISK FACTORS

We analyzed the following endpoints which represent a risk to the health and safety of self and others:

- Self-inflicted injuries: Trying to injure oneself, on purpose, in the previous 12 months.
- Alcohol abuse: Having “five or more drinks of alcohol in a row, that is, within a couple of hours,” on one or more days, during the previous thirty days.
- Daily smoking: Smoked one or more cigarettes daily, over the previous 30 days.
- Use of drugs: Use of cocaine, including crack, LSD, PCP, ecstasy, mushrooms, speed, ice, or heroin, in the previous 12 months.
- Over-the-counter medication abuse: Having taken an over-the-counter medicine to get high or just to see what it felt like, one or more times.
- Runaway: Having been away from home without the parent’s or guardian’s permission for at least one entire night, 6 or more times in the previous 12 months.
- Hurting animals: Physically hurting animals on purpose, in the previous 12 months.
- Hurting people: Physically hurting someone on purpose, in the previous 12 months.
- Fire setting: Has set fires, to damage something of value, in the previous 12 months.
- Carried a weapon to school: Has carried a weapon such as a gun, knife, or club, on school property, one or more times, in the previous 30 days.
- Weapon use: Has used a weapon that could seriously hurt someone, in the previous 12 months.

The data were analyzed utilizing the Data Analysis System (DAS) of the Inter-University Consortium for Political and Social Research at the University of Michigan. This is an online

analysis system that allows users to run both simple and complex analyses, recode and compute new variables, and subset variables or cases for downloading. The software powering the system, the Survey Documentation and Analysis (SDA) system, was developed and is supported by the Computer-assisted Survey Methods Program (CSM) at the University of California, Berkeley (29,30).

We analyzed the frequency distributions to determine the demographic characteristics of students participating in bullying behavior and the frequency of the health, safety and educational risks in relation to involvement in bullying behaviors. Logistic regression analysis was conducted using the SDA Logit/Probit Regression Program, to examine associations between bullying behaviors and the health, safety and educational risks. Each multivariate logistic regression included gender, grade, race, as well as health and safety risks. Adjusted odds ratios (OR) and standard errors (assuming simple random sampling) were calculated.

OUR FINDINGS

Twenty-three percent (876) of the 3,744 (876 + 2,868) students who participated in bullying, as bullies and/or victims in the previous 12 months, experienced a cluster of depression, irritability, anxiety, sleeping difficulties, and one or more physical symptoms -- headaches, stomach aches, back aches, or dizziness (Table 1). They represent nine percent (876/9,574) of US students in grades 6, 8, and 10, with a predominance of females who are attending 8th and 10th grade. A similar demographic pattern was evident among the seven percent of students (715) who suffered from the same cluster of physical and emotional symptoms but did not participate in bullying in the previous 12 months. In contrast, their peers who participated in bullying but did not suffer physical and emotional symptoms were predominantly males.

A considerable segment (35-45%) of students, who suffered from a cluster of symptoms linked to bullying, hurt themselves or other people on purpose, abused alcohol, or abused over the counter medications (see table 2). Furthermore nine to twenty-four per cent of these adolescents were involved in runaway episodes, daily smoking, use of drugs, setting fires, hurting animals on purpose, carrying a weapon to school, or using a weapon to hurt others.

Above all, students who suffered from bullying-related physical and emotional symptoms were reported to have been involved in risk behaviors that occurred, except for alcohol abuse and daily smoking, at rates of prevalence that were two to seven times more frequent than those reported by their peers who were not involved in bullying and did not experience psychosomatic morbidity. Furthermore risk behaviors among students with bullying related symptoms occurred one and a half to three times more frequently than among their peers (a) who participated in bullying without experiencing symptoms or (b) who had such symptoms but did not have a recent history of bullying.

The risk of self-inflicted injuries is strikingly higher among students with bullying related symptoms (OR 8.14) than among those involved in bullying without the associated symptoms (OR 1.63) or among those who suffered from symptoms not associated with recent bullying (OR 3.41) (Table 3). Also, the chance of hurting other people on purpose is significantly higher among adolescents with bullying related symptoms (OR 4.20) than among peers who were

involved in bullying without having those symptoms (OR 3.42), or among those who suffered from symptoms but without recent involvement in bullying (OR 1.76).

Within the group of adolescents who suffered psychosomatic morbidity associated with participation in bullying, we can distinguish between those who are bullies only, victims only, and both bullies and victims (see table 4). Those who are both bullies and victims have the highest risk of self-inflicted injuries (OR 11.21), followed closely by their peers who are only victims of bullying (OR 10.33) and, to a lesser extent, by those who only bully others (OR 7.35) (see table 4).

Table 2. Health and safety risks in relation to bullying behaviors and symptoms

Health, and safety risks	Total N (unweighted) N=9574	Students who are bullies and/or victims and have symptoms N=876	Students who have symptoms and are not involved in bullying N=715	Students who are bullies and/or victims and do not have symptoms N=2868	Students who are not involved in bullying and do not have symptoms N=5115
Self-inflicted injuries	1139	43.4%	22.5%	12.5%	5.6%
Hurt other people	1942	45.7%	20.5%	31.7%	11.9%
OTC medication abuse	968	35.3%	16.7%	10.9%	5.2%
Alcohol abuse	1506	42.1%	34.5%	36.8%	26.9%
Runaway	1103	24.0%	13.6%	16.7%	6.8%
Daily smoking	414	15.2%	15.7%	12.6%	10.1%
Use of drugs	689	19.3%	10.2%	9.0%	2.9%
Hurt animals	674	10.6%	6.3%	8.4%	3.7%
Setting fires	328	8.6%	4.7%	6.2%	1.4%
Carried a weapon to school	749	15.7%	6.7%	11.3%	2.8%
Used a weapon	952	24.3%	7.4%	13.6%	.5%

All frequencies with a chi-square p-value of less than 0.05 are represented in bold.

All percentages (%) are column percentage of each Bullying and symptoms category.

Data: Health Behavior in School-aged Children, WHO 1996.

On the other hand, the risk of hurting other people on purpose is especially high among those who bully others (OR 7.51), followed by those who are both bullies and victims (OR 5.65) and, to a lesser degree, by those who are victims only (OR 3.40) (see table 4).

The risk of abusing over the counter medications is especially high among students who are victims (OR 4.02) and those who are both bullies and victims (OR 3.09). The probability of carrying weapons to school is particularly high among those students who bully others (OR 3.39) (see table 4).

DISCUSSION

This study highlights the occurrence of a constellation of physical and emotional symptoms experienced by adolescents who have been bullied and/or have bullied others, inside and out of

school. These students involved in bullying have reported being depressed every day for at least a two week period, as well as experiencing, at least once a week, a bad mood or irritability, nervousness, or sleeping difficulties; and at least one or more physical symptoms such as headache, stomach ache, dizziness, and/or back aches.

Table 3. Relative health and safety risks: Adjusted odds-ratios (and standard errors)¹

Health and safety risks²	Students who are bullies and/or victims and have symptoms³	Students who have symptoms and are not involved in bullying³	Students who are bullies and/or victims and do not have symptoms³
Self-inflicted injuries	8.14(1.20)	3.41(1.24)	1.63(1.20)
Hurt other people	4.20(1.19)	1.76(1.23)	3.42(1.15)
OTC medication abuse	2.53(1.20)	2.57(1.23)	1.04(1.17)
Alcohol abuse	0.84(1.19)	0.97(1.19)	1.10(1.14)
Runaway	1.31(1.25)	1.42(1.26)	2.61(1.17)
Daily smoking	0.68(1.29)	1.31(1.29)	0.86(1.21)
Use of drugs	1.38(1.24)	0.65(1.29)	1.26(1.19)
Hurt animals	1.07(1.39)	3.37(1.44)	1.47(1.29)
Setting fires	0.93(1.45)	1.18(1.60)	1.87(1.33)
Carried a weapon to school	1.36(1.25)	0.51(1.47)	2.10(1.24)
Used a weapon	1.18(1.30)	0.86(1.36)	0.62(1.20)

¹ Each multivariable logistic regression has gender, race, grade, and all other health and safety risks in the model.

² Row reference group is students who do not exhibit the respective health, safety risk.

³ Column reference group is students who are seldom involved (once or twice per year) or are not involved in bullying as bullies and/or as victims, and do not have symptoms.

All adjusted odds-ratios larger than twice the standard error are represented in bold.

This combination of phenomena raises the question of the existence of a possible nosological entity, affecting almost ten per cent of U.S. adolescents. That group of adolescents runs a substantially higher risk than their peers of inflicting injuries on themselves and of hurting others on purpose, especially if they bullied others or were both bullies and victims.

The methodology utilized here, analysis of non-clinical cross-sectional survey data, has significant limitations. It allows us to establish a link between bullying and morbidity, but it does not let us determine causality. Furthermore, with the present data we are unable to ascertain the occurrence of other forms of victimization, determine family antecedents, or diagnose medical or psychiatric conditions that precede or follow the participation in bullying. Moreover, the database used in this study has not allowed us to investigate the association of bullying with other forms of morbidity previously reported or seen in clinical practice such as injuries, anorexia or bulimia, nightmares, hallucinations, or flashbacks.

Table 4. Relative health and safety risks for different types of involvement in bullying behavior: Adjusted odds-ratios (and standard errors)¹

Health, and safety risks²	Students who are bullies and have symptoms³	Students who are victims and have symptoms³	Students who are bullies and/or victims and have symptoms³
Self-inflicted injuries	7.35(1.31)	10.33(1.35)	11.21(1.27)
Hurt other people	7.51(1.30)	3.40(1.36)	5.65(1.26)
OTC medication abuse	1.49(1.31)	4.02(1.35)	3.09(1.28)
Alcohol abuse	1.72(1.30)	0.30(1.39)	0.91(1.26)
Runaway	1.47(1.36)	0.85(1.57)	1.52(1.34)
Daily smoking	0.61(1.43)	1.37(1.56)	0.87(1.40)
Use of drugs	3.1(1.35)	0.50(1.55)	0.81(1.36)
Hurt animals	1.47(1.59)	0.58(1.89)	1.10(1.50)
Setting fires	1.49(1.70)	0.45(2.35)	1.32(1.55)
Carried a weapon to school	3.39(1.39)	0.35(1.76)	0.60(1.48)
Used a weapon	1.01(1.41)	1.80(1.45)	1.13(1.35)

¹ Each multivariable logistic regression has, gender, race, grade, and all other health and safety risks in the model.

² Row reference group is students who do not exhibit the respective health, safety risk.

³ Column reference group is students who are seldom involved (once or twice per year) or are not involved in bullying as bullies and/or as victims, and do not have symptoms.

All adjusted odds-ratios larger than twice the standard error are represented in bold.

Future longitudinal clinical studies will be able to clarify if (a) students with a history of bullying but without morbidity, (b) those with symptoms associated with bullying and (c) those with symptoms not linked to bullying in the previous year, represent three distinct independent groups or whether they correspond to different stages in the clinical effects of bullying from 6th to 10 grade. Also it will be possible to establish at what age bullying related symptoms begin to manifest themselves in children and whether they persist into adulthood. In addition, forthcoming investigations may explain to what degree the physical and emotional symptoms related to bullying are expressions of a Post-traumatic Stress Disorder and/or other psychiatric entities preceding or resulting from bullying, as well as a possible role for gender in enabling or preventing a link between participation in bullying and morbidity.

CONCLUSION

We hope that this study elicits further examination and debate about the existence of a nosological entity linked to bullying. Pending further research, the present results should support the desirability of ascertaining participation in bullying, as a bully and/or as a victim, in all pediatric visits. Furthermore there is a need to inquire about symptoms and risks related to this form of abuse.

Chapter 84

DEATHS LINKED TO BULLYING AND HAZING

Jorge Srabstein*, MD

Division of Psychiatry and Behavioral Sciences,
Children's National Medical Center, Washington, DC, US

ABSTRACT

The purpose of this chapter was to determine the extent of news reports of deaths associated with bullying and hazing, among young people, over a period of fifty seven years. This study was based on a survey of death events linked to bullying or hazing, reported in English newspapers from January 1, 1950 through December 31, 2007. The search was based on the review of major US and world publications, written in English, utilizing the terms "bullying, hazing, ragging and death." the last 57 years, there were at least 250 reported cases of deaths, linked to bullying, hazing or ragging, reported in English language newspapers from around the world. In seventy-six per cent of these news stories (n=121), there was an alleged history that the victim was bullied. Twenty-two per cent (n=55) of these reports were associated with suspected hazing or ragging. In only four cases (2%) those who died had a history of bullying others. The majority of the reports of bullying related deaths (62.3%) originated in Europe, and most of them (93%) occurred in the United Kingdom. Sixty-seven percent of bullying-related deaths were reported in the last 10 years. The significant increment in news reports concerning deaths associated with bullying, may be the result of a rise in public awareness about the lethal aspects of this type of maltreatment. There is an urgent global public health need to ascertain regional mortality prevalence related to bullying and hazing, along the lifespan.

INTRODUCTION

There is an evolving research which is documenting, that bullying is significantly linked to the main causes of death among young people, such as suicide, accidents and homicide (1-9). It has been estimated that American adolescents who were involved in bullying others and/or being bullied at least three or more times, in the previous 12 months, were 2.1 to 7.1 times at

* Corresponding Author's Email: jsrabste@cnmc.org.

higher risk of suffering from self injuries than their peers, who did not participate in bullying or were very infrequently involved in these behaviors (7). This same study also showed that those adolescents, who were bullies and/or victims were 1.3 to 2.4 times at higher risk, of experiencing injuries that were accidental or perpetrated by others.

To date there are no published studies documenting the prevalence of mortality linked to bullying. Neither has there been any concerted attempt to measure the degree of public awareness about the lethal aspects of bullying. This in spite of cases of death associated with bullying reported worldwide (10-14).

The objective of the present study was to ascertain, over a long period of time, the extent of news reports of deaths among young people associated with bullying and hazing.

DATA USED

This study is based on a survey of death events linked to bullying or hazing, reported in English language, newspapers, from January 1, 1950 through December 31, 2007. The database was created through a search conducted with the use of LexisNexis Academic (15), which was accessed through the Washington Research Library Consortium (WRLC) I, a regional resource-sharing organization established by some of the major universities in the Washington, DC metropolitan area. This study was considered exempt from Institutional Review Board approval because the database is available in the public domain.

The search was based on the review of major US and world English language publications, utilizing the terms 'bullying or hazing or ragging and death'. The concept of hazing was added to this study, as a form of bullying in which young adults are dared to, challenged or urged to do something risky, in order to secure approval and inclusion by the members of a group (16). The term "ragging" is used in India, Pakistan and Sri Lanka, to indicate hazing of newcomers to an educational institution.

For inclusion in this study, a published story was required to have documented the victim's or victimizer's name, age, gender, date of death, location and information indicating that the death was allegedly linked to bullying, hazing or ragging. This information was necessary to avoid entries of different stories pertaining to the same event.

The victim or the victimizer was required to be between the ages of 10 and 25 years, in order for the reported death to be included in the present report.

FINDINGS

There were at least 250 reported cases of death, linked to bullying, hazing or ragging, reported in English language newspapers from around the world, in the last 57 years. In seventy-six per cent of these news reports (n=121) there was an alleged history that the victim was bullied. Twenty-two per cent (n=55) of these reports were associated with suspected hazing or ragging and in only four cases (2%) did those who died, have a history of bullying others (see table 1).

There was a preponderance of males (65.45%) whose death was linked to bullying. This pattern was even more dramatic among the victims of hazing (92.73%) and those who bullied others (100%).

Table 1 shows a gradual decline in the frequency of deaths associated with bullying, from among the young teenagers (45.55%) to the young adults (18.32%). Most of the fatalities from hazing were late adolescents (10.90%) or young adults (87.27%).

The majority of fatalities connected to a history of bullying (67%), were reported in the last ten years. News of deaths linked to hazing seemed to be almost evenly distributed over the last 2 decades. The majority of the reports of bullying related deaths (62.30%) have originated in Europe, most of them (93%) having occurred in the United Kingdom. There was a significant number of reports of hazing (80%) occurring in the Western Hemisphere, primarily in the United States.

As shown in table 2, among the deaths attributed to bullying, most of the deceased (77%) killed themselves, and/or killed others, while 18% died of homicide and 5.2% died of unintentional causes, including car or train accidents, drowning, overheating, or a non-proximate cause of death, such as anorexia linked to bullying.

Eighty-five per cent of hazing-related deaths were due to accidents, where alcohol intoxication was frequently the cause or a significant factor of the fatality.

* Column percentages.

DISCUSSION

This is the first documented look at the array of cases of deaths attributed to bullying or hazing, reported in the news for a period of over half a century. However these 250 fatalities among young people, do not represent and may underestimate the global mortality prevalence linked to this form of maltreatment. The increased number of reports published in the last 10 years and/or the higher frequency of them originating from the United Kingdom are perhaps, manifestations of increased regional awareness about the toxicity of bullying. This, in turn, may contribute to higher community alertness in every case of youth suicide, homicide and lethal accident, to make inquiries to ascertain whether or not there is a link to a history of bullying, harassment or intimidation. Similarly, in the United States, concerns were raised about the use of hazing, following accidental deaths among university students, especially if there was a history of alcohol intoxication, in the case.

The impressive public health implications of these 250 cases of reported deaths are magnified in those cases where the victims of bullying committed massive killings prior to their own suicide (17-18).

The impact of the Columbine High School massacre in 1999 reverberated across the world (19-24). This and similar tragedies led, to the implementation of anti-bullying laws in different jurisdictions of the United States (25). The text of most of these statutes, did not reflect the public health concern about the lethal links of bullying (26)

Public memory and sensitivity about the association between bullying and death is again rekindled in 2007, with the Virginia Tech shootings (18). Unfortunately, the lessons of these episodes fade away in the collective memory of the public and its policy makers.

Forty-six years ago, Kempe et al. (27) alerted the world medical community about the mortality of child abuse, until then an already known condition (28) yet an ignored phenomenon by the public. The publication by C Henry Kempe (1922–1984) highlighted the dramatic lethal issues associated with child abuse, bringing to the forefront a condition that for the previous sixteen years was only known through its morbidity (28).

Forty-six years later, there is an urgent need to ascertain the regional prevalence of mortality associated with other forms of maltreatment such as bullying and hazing. The present study is being published as an attempt to emphasize this global public health imperative.

Chapter 85

INTERVENTIONS TO REDUCE BULLYING

Ken Rigby*, PhD and Phillip Slee, PhD

School of Education, University of South Australia, Underdale,
South Australia, Australia

School of Education, Flinders University, Adelaide, South Australia, Australia

ABSTRACT

Recognising the potential health risk of bullying in schools, numerous anti-bullying interventions have been developed. These have been designed to prevent bullying from happening and/or to stop bullying from continuing once it has occurred. Evaluations of the effectiveness of such interventions indicate some positive effects in reducing the level of bullying in schools and in stopping cases from continuing. Alternative approaches and intervention methods are reviewed and their reported effectiveness examined. Factors considered relevant in the choice of method are discussed, such as the severity of the bullying, the age of the child and the thoroughness of program implementation.

INTRODUCTION

Over the past two decades the steady accumulation of evidence of the prevalence and harmfulness of school bullying has led educators and health professionals to recognize that peer victimization in schools is a serious problem. Throughout the world steps have been taken to address the problem. For example, in Australia, the Commonwealth Government has provided the National Safe Schools Framework, which contains a set of nationally agreed principles for a safe and supportive school environment and includes guidelines to assist schools in addressing issues of school bullying. A growing number of anti-bullying programs have now been developed worldwide and, in some cases, rigorously evaluated and conclusions drawn about their effectiveness. These have provided a basis for an evidence-based approach in selecting

methods of intervention that can effectively reduce school bullying. The aim of this paper is to examine what is known about anti-bullying interventions and their effectiveness and to suggest how such knowledge can be applied.

BULLYING DEFINED

Bullying has been conceived broadly as the systematic abuse of power (1). It is a form of aggressive behavior perpetrated by a more powerful individual or group that is unfair or unjustified and is typically repeated. Bullying may be classified as direct, as in face-to-face physical and verbal harassment, or indirect, as in unfair exclusion, rumour spreading and the use of electronic means to threaten or harm someone. This latter form is commonly known as cyberbullying and can include the sending of instant or email messages, images, videos, calls, excluding or preventing someone from being part of a group or an online community. The severity of bullying extends along a continuum from acts that are comparatively mild, as in insensitive teasing or taunting, to extremely severe, as in repeated violent physical assaults, death threats or deliberate and unjustifiable total exclusion by peers.

KINDS OF INTERVENTIONS

Interventions may be categorised broadly according to whether their purpose is primarily to prevent bullying from happening or alternatively to deal with cases of bullying if and when they occur. However, a rigid distinction cannot be made; for instance, disciplinary actions taken when a case of bullying is identified may impact not only upon the person being treated but may also make it less likely that others will bully; that is, it may also have a preventative function. Some interventions are not primarily directed towards changing the behaviour of individuals who become involved in bullying, but are concerned rather with establishing an environment or ethos in which bullying is less likely, for instance by developing in members of the school community (including both teachers and parents) a better understanding of the problem and promoting more pro-social attitudes and empathic feelings towards others; or alternatively by reducing the motivation to bully by involving students more deeply in school-related study. These may be described as preventative measures. Many programs include both preventative and interventive elements.

PREVENTATIVE MEASURES

Some preventative measures are educational in nature. For example, a Finnish intervention (2) contains preliminary training sessions with teachers during which facts are presented about bullying and feedback is provided from surveys conducted with the teacher's own classes. Subsequently, teachers conduct discussions with their classes designed to raise awareness of the problem and foster commitment to reducing bullying behaviour. For example, students may be encouraged to assist their peers when they see them being bullied in some way. In some anti-bullying programs (3,4) selected students are provided with special training to help more

effectively as peer supporters. Preventative measures may also include working with parents to mobilise their support (5-7).

As part of curriculum work, some initiatives have sought to develop certain qualities or attitudes in children that are seen as inimical to bullying others. For instance, a program employed with young children focussed on helping them to develop higher levels of empathy and to control angry impulses (8). Another program with elementary school children (9) sought to reduce bullying by involving students in cooperative problem-solving. Here we may note that ‘dosage’ level involved in the application of such interventions may be important. This may be reflected for instance in the required number of classroom discussion meetings with children.

Less directly, efforts have been made to reduce bullying by training teachers to become more effective classroom managers (10). The skills and qualities seen as basic to such management include the modelling of care for students as individuals, clear indications being provided of what students are expected to achieve, careful monitoring of both progress in school work and the children’s social relations, and conducting sensitive intervention when necessary to address behavioural problems. It has been observed that supportive teacher–student relationships provide a protective buffer that mitigates negative effects; that is, teachers can build the resilience capabilities of ‘at risk’ students (11) Teachers, through their actions can create and set expectations for respectful and inclusive behaviour, and provide success-oriented classroom environments and learning experiences. The achievement of a positive classroom climate in which students are well motivated and interested in their work is seen as an important factor in reducing bullying (12).

Preventative methods also include helping vulnerable students to acquire social skills that enable them to cope more effectively with bullying behaviour. To do so requires both the identification of effective and non-effective strategies employed by students and the teaching of appropriate ways of coping (13.)

INTERVENTIONS ADDRESSING CASES OF BULLYING

What to do when cases of bullying occur is controversial, with some favouring firm disciplinary action directed at the perpetrator, and others favouring a more non-punitive or mediational approach. Results from on-line surveys conducted in the United States and Australia indicate that disciplinary means of reducing bullying behaviour are seen as appropriate by most teachers and school counsellors, even in cases of low severity bullying (14,15).

An example of the application of a disciplinary approach utilising ‘rules and consequences’ was implemented and evaluated in Oregon, USA (16), when middle school students were taught appropriate social behaviours. They were commended and reinforced for observing these rules; certain mildly negative consequences were applied when rules were violated. This approach is broadly similar to that adopted in numerous programs, including those evaluated by Olweus in Norway (17) as well as by those who have followed his lead in the USA (18), in Switzerland (19), in Belgium (20) and in Germany (21).

Appropriate consequences for rule violations are generally determined by the staff of a school. However, some schools have elected to involve students in the process of determining

how bullies should be disciplined. This approach has been adopted in a small number of schools in the United Kingdom (22). Student representatives constitute a court at which students accused of bullying are 'tried' by their peers according to a clearly defined procedure with some guidance from school staff. Appropriate penalties or sanctions are recommended by the court and these may be implemented by the school.

Recognising the fact that bullying tends to stop when student observers voice their objection, programs have been developed to train students to play a positive role as bystanders to discourage bullying behaviour when they see it happening (2,4).

Restorative justice practices have been used to address cases of bullying in some countries, including England, Australia and the United States (23). These practices are commonly seen as non-punitive and are directed towards improving the relationships between students who are in conflict. The intention is to help the child who is bullying to recognize the need for the restoration of acceptable relations, for example by making a sincere apology, and subsequently engaging in positive behaviour towards that person. An essential aspect of this approach is get the bully to appreciate the harm he/she has done and to recognize that community acceptance is contingent upon restorative action. In cases of extreme bullying, community conferences may be held involving not only the 'bully', but also the 'victim' and friends, supporters and parents of those involved (24).

Less directive than restorative justice, there are two other methods that seek to achieve the same end, that is the restoration of positive relations that have been damaged by bullying. These are the Support Group Method (25,26) and the Method of Shared Concern or Pikas Method (27,28). In both methods the bully or bullies are informed about the harm that has been done to a person who has been targeted. No accusations are made, but it is clearly communicated that their help is expected in order to improve matters. With the support group method children other than those suspected of having engaged in the bullying are present at a meeting convened by a teacher or counsellor. The Method of Shared Concern is a multi-stage process in which the suspected bullies are first interviewed individually; subsequently group meetings are held which may include the victim to reach a mediated solution (29,30).

WHOLE SCHOOL APPROACHES

Commonly schools employ a range of methods, some of which may be called 'preventative' and others primarily interventive in the sense of addressing actual cases of bullying. When these different elements are put together in a complementary fashion, they are often called a 'whole school approach.' This phrase also has connotations indicating that a collaborative and systematic approach has been adopted. This is made explicit in the school anti-bullying policy. A good example is the approach pioneered by Olweus (5) and adopted widely in many countries. This approach differentiates between the work done at different levels: at the level of the school, as in educating the school community about bullying and developing an appropriate anti-bullying policy; at the level of the classroom, as in conducting discussions with students to develop acceptable rules relating to their behaviour with other students; and at the level of individual children, as in dealing with children who have become involved in bully/victim problems. In some programs, a further dimension has been recognized,

that of engagement with the wider community and especially with families whose children are at risk of involvement in conflicts at school (6).

THE ROLE OF SCHOOLS AND RESEARCHERS IN IMPLEMENTING PROGRAMS

Anti-bullying programs that have been evaluated thus far have been for the most part conducted in accordance with the requirements of a pre-designed program. The degree of direction by researchers has varied. The Olweus anti-bullying program for instance contains clear instructions as to how the program is to be implemented. By contrast, the Sheffield Project in England (31) required participating schools to undertake some specified actions, for example, the development of an agreed anti-bullying policy, but allowed some choice from a range of optional methods about which the schools were provided information and/or training. This 'smorgasbord' approach resulted in some variety in what was done, for example some adopted the Method of Shared Concern, but others did not. Allowing schools to show some initiative in what they did in countering bullying arguably increased their sense of ownership of the project. Some programs have involved the researchers in providing continuous advice and guidance. Comparisons made between outcomes for Flemish schools receiving or not receiving such continual attention suggests that additional external 'support' may not be beneficial (20).

PROGRAM EVALUATION

Over the last ten years there has been a notable increase in reports which have attempted to evaluate interventions to reduce bullying. Many of these have made use of rigorous research procedures involving careful measurement of relevant variables such as rates of bullying, and the employment of research designs that enable one to make reliable estimates of changes in bullying behaviour that can be attributed to specified intervention methods. This has typically involved the use of control groups that enable one to compare changes that occur over a period in intervention or experimental groups with changes that naturally occur, when no intervention takes place, for example due to maturational effects. It is well known that reported bullying declines as children mature (5) and such a decline has sometimes been wrongly attributed to the intervention. An acceptable research design, known as a time-lagged cohort design, has been used in some evaluations of interventions. This requires that comparisons of the outcomes following an intervention with what has been found to be the case for an equivalent non-intervention age group assessed earlier (32). For the most part, the data used in these evaluations have been derived from self-reports of students; in a few studies from teacher assessments, direct observations or peer nominations of children involved in bullying.

Brief summaries of reports concerning 32 interventions that have been evaluated are given in Table 1. They have been categorised as (A) employing a whole school approach (A1- A21) (B) working with students through the school curriculum (B1 – B4) and (C) tackling or treating cases of bullying (C1 to C6) and (D) applying effective classroom management (D1).

Table 1. Summary of initiatives of school to reduce bullying

A. Whole school approaches

Name of study	Nature of programme	Participants	Assessment method(s)	Design	Main outcomes
1. Bernese study in Switzerland (19). Conducted 1997-1998.	Modeled on Norwegian study reported by Olweus (1993) with emphasis on rules in the context of whole school approach	Eight kindergartens (N=152) received the program. Another 8 kindergartens (N=167) acted as controls. Children aged 5-7 years	• Teacher rated children • Children nominated peers as bullies and/or victims	Pre-test, post-test, control group design. Data collected at the start and end of the school year	Teachers indicated decrease in physical bullying and indirect bullying, but increase in verbal. Children indicated increase in victim and bully nominations in control group and a reduction in intervention group
2. The Toronto, Study (64) Conducted 1992-1995	Focused on the school, parents, classroom and individuals, following Olweus' model	4 primary schools (N=898) students aged 8-14 years	• Student questionnaire	One pre and one post intervention (after 18 months)	Small reductions in reported level of being bullied. Increases in bullying others
3. Finland study conducted in Turku and Helsinki (2) Conducted 1999-2000	Teachers trained 1) to develop policy 2) provide curriculum work with classes 3) intervene with individual bullies	48 school classes from 16 schools received program; 24 classes served as controls. Students aged 9 to 12 years	• self-report questionnaire • peer-nominated questionnaire	Pre-test, post-test control group design; retest after 6 months.	Significant reduction (16%) in reporting being bullied; increase (15%) in control group. Decrease greatest among youngest students

Name of study	Nature of programme	Participants	Assessment method(s)	Design	Main outcomes
4. The Texas Study Expect Respect (65) Conducted 1998-2000.	Five components: 1. Classroom education 2. Staff training 3. Policy/ procedure development 4. Parent education 5. Support services	Fifth graders (N=1109) from 6 intervention and 6 comparison schools. Respondents about 11 years of age	• Student questionnaires, answered on 3 occasions. • Focus groups separately for girls, boys and teachers of 5th grade students	Pre-test, post-test control group design (Note that only 60% of participants completed the 3 assessments).	No significant increase in knowledge of bullying. Increased reporting of bullying occurring. Students reported they were more likely to intervene personally
5. The Norwegian Project (5) from May,1983-May 1985 as evaluated in the Bergen sample	Multi-pronged approach, involving preventative work through staff education, policy development, classroom discussions. Cases of bullying addressed by applying rules and appropriate sanctions.	42 primary/secondary schools with 2500 students aged 11-14 years	• Student questionnaires • Teacher ratings	Cross-lagged study with two post intervention assessment (after 8 and 20 months)	Substantial reductions in self-reported bullying (up to 50%) and reduction in other anti-social behaviours
6. The Norwegian Project, as evaluated in the Rogaland sample conducted in 1986 (33)	As reported by Olweus (see above)	37 primary and secondary schools, with approximately 7000 students.	• Student questionnaires • Interviews with teachers on degree of implementation of the program.	Pre-test, post-test design. Re-testing after 3 years.	Increase in bullying over time, both in being bullied and bullying others. More positive outcomes for schools implementing programs fully.
7. New Bergen Project (5) in Norway (1997-98)	Olweus Intervention Program	Grades 5-7 involving 3,2000 students from 14 intervention schools and 16 comparison schools	• Student questionnaires	Pre-test. Post-test control group design, with re-test after 6 months	Reductions in 'bully/victim' problems in the intervention schools on average between 21 and 38%.

Table 1. (Continued)

Name of study	Nature of programme	Participants	Assessment method(s)	Design	Main outcomes
8. Oslo Project Against bullying (5) (1999-2000)	Olweus Intervention Program	Students in grades 5-7 and 9 involving 2,300 students	Student questionnaires	Pre-test post test design	Reductions in Years 5-7 after 1 year in overall being bullied of 42% and reductions in bullying others of 52%
9. The New National Initiative against Bullying, Norway (5) (2002-2002)	Olweus Intervention Program	Students (N = 21,000) from Grades 4-7 from more than 100 schools nationally	Student questionnaires	Pre-test, post-test design with comparison (baseline) group	After 8 months reduction of 34% in reportedly being victimised and 43% in engaging in bullying.
10. The Olweus Bullying Program as evaluated in US public middle schools in Seattle.(34) conducted 2002-2004	Olweus intervention Program	Seven intervention schools and 3 control schools catering for middle school children	Student Questionnaires focussing on relational bullying (eg. Spreading rumours, social exclusion)	Pre and post tests controlling for baseline prevalence. Some in depth interviews with students	No overall effect evident on student victimization; however significant reductions for sub-groups, eg., white (but not black) students
11. The Home Office Study, Liverpool and London, England (66). Conducted 1991-1993	Developed anti-bullying policy, emphasised peer support and assertiveness training	4 intervention schools: 2 primary and 2 secondary in Liverpool and London. Students aged 8-16 years	Self report student questionnaire	Pre intervention and post intervention testing (2 years after start of programme). No control students	

Name of study	Nature of programme	Participants	Assessment method(s)	Design	Main outcomes
12. The Seville Study, Spain (6) conducted 1995-2000	Community approach with components to promote democratic values, cooperative group work, working with families, empathy and concern for others	9 primary and secondary schools. Students aged 8-18 years (N=1171)	Student questionnaires assessing behaviour, attitudes and (at the end) effectiveness of aspects of the program	Some 5 schools used for pre and post intervention testing, compared with 4 control schools (post tested only)	Reported significant reductions overall in pupils involved in bullying (but not for specific kinds of bullying).
13. The Flanders Study, Belgium (20) conducted 1995-1997		18 schools; 1104 students. (Note for main analyses only 12 schools used). Students aged 10-16 years	Student questionnaire	Three conditions each with 6 schools: intervention with support; intervention without support; and control. Tested post intervention after 8 and 20 months	Reduction in bullying in primary schools relative to controls. No change in secondary schools. No difference due to support from researchers
14. Western Australia : Friendly Schools (67) Conducted 2000-2002)	Emphasis upon social skills development especially through classroom curriculum work, promotion of peer support, advice to families and teachers on intervention techniques, such as the Method of shared concern	Primary school children Grades 4 and 5, mean age of 9 years (N = 2,068)	Student questionnaires, including self-reported bullying-related behaviours and attitudes to victims, adapted from Rigby(1998) and Rigby and Slee (1991)	Pre-test, post test, control group design	No overall reduction in frequency of self-reported bullying or bullying others, but significant reductions reported on some specific indices, eg being ignored and being called hurtful names.
15. South Eastern United States (18) Conducted 1995-1997.)	The Olweus Bullying Prevention Program	Two groups of schools with children aged 11-13 years: A, approx 3000; B, approx 2000. Note work with Group	Self- report questionnaires	Pre-test, post test design with baseline comparisons	For Group A schools, significant reductions in reported being bullied among boys (but not girls) after one year. After two

Table 1. (Continued)

Name of study	Nature of programme	Participants	Assessment method(s)	Design	Main outcomes
		A extended over 2 years; for Group 1 for only one year			years, no effect evident. For Group B no significant effects on bullying behaviour reported.
16. O'Moore et al (68) Ireland conducted in 1993-94.	Training of teachers in classroom management and the provision of advice to parents	Students in Donegal, Ireland in years 3 to 5 (approx 500 respondents)	Self-report questionnaires	Pre-test post test, but without a control group. (Hence unclear whether reductions were due to maturation effects)	A reduction of 19.6% in reports of being victimized and 17.3% in bullying others.
17. Prevention of bullying in German schools (21). Conducted 1994-1996.	The Olweus Bullying Prevention Program	Students in 37 schools in Schleswig Holstein in grades 3 to 12. (N= 11,052 in baseline and 10,610 in post test)	Self report questionnaires	Pre-test post test but with no control group (disallowed on ethical grounds)	Significant reductions for respondents engaging in low level bullying, but not high level bullying; nor for indirect bullying; nor for older students.
18. Anti-bullying interventions in Kempele, Finland. (69) Conducted 1990-1998)	Community-based, team approach involving parents, teachers and students	In total 2,729 students participated aged 10-14 years (from 4 th to 7 th grade)	Self-report questionnaires	Pre-test post test with comparisons made with results for equivalent age groups.	Significant reductions in bullying reported after one year, sustained over the next 7 years.
19. Steps to Respect, US, (70) Conducted 1998-2000.	Staff training, use of a classroom curriculum focussing on socio-emotional skills, engagement of parents	Students in Grades 3 - 6 (N= 1,123)	- Self-report questionnaires - Playground observations	Experimental and Control groups tested pre and post.	Self-report data did not indicate reductions in bullying behaviour; unlike playground observations which did.

Name of study	Nature of programme	Participants	Assessment method(s)	Design	Main outcomes
20. The Peace Pack Intervention in South Australia (7).	Teachers advised and guided in the application of the Peace Pack, containing advice on policy development and curriculum work	Students (N approx 950) from 4 primary schools attending Grades 1 to 7.	self-report questionnaire	Pre-test post test, no control group.	After one year there were more children reporting being bullied less than being bullied more and more reported feeling safe at school.
21. The Sheffield Study, England (31) Conducted 1991-1993	Whole school approach including both core and optional components	16 primary and 7 secondary school students aged 9-16 years, total N = 6,500	Self report questionnaires and interviews with teachers.	Pre-test, post test control group	After 18 months victimization rates decreased by 14% in primary and 7% in secondary schools.

B. Working with students through the curriculum

Name of study	Nature of programme	Participants	Assessment method(s)	Design	Main outcomes
1. The Chicago Study, United States (8) Conducted 1998	The Second Step Program. Use of curriculum to develop knowledge and skills related to bullying behaviour	Children in 5 classes in preschools and kindergartens aged 3-7 years (N =109)	- Interviews with children - Teacher ratings of skills and behaviours - Behavioural observations.	Pre-test, post-test design (after 6 months)	Increase in children's knowledge of conflict situations Observed reduction in children's aggressive behaviour.

Table 1. (Continued)

Name of study	Nature of programme	Participants	Assessment method(s)	Design	Main outcomes
2 The Sheffield (England) Cooperative Learning Study (9) Conducted 1991-	Implementation of methods of cooperative group work (CGW)	2 schools and 16 classes; a total of 149 students aged 7-12 years	Children nominated peers as bullies and/or victims from a list provided	Intervention classes doing CGW (N=11) compared over 2 years with control classes (N=5)	No significant effect of intervention on bullying behaviour (increase in both groups). Small decrease in reporting being bullied in intervention classes
3. Promoting positive bystander behavior in Finland (2) Conducted 1999-2000	Teachers trained Students to undertake interventions as bystanders to discourage bullying	Primary school students from 16 schools involving 1,220 children in Grades 4, 5 and 6	- self-report questionnaire - peer-nominated questionnaire	Time lagged comparisons between age equivalent cohorts	Significant reductions in self-reported victimisation, especially in Grade 4 and in schools where procedure more thoroughly implemented.
4. Support Group (befriending) project in Italy (4) Conducted 1998-1999	Selection and training of students as peer supporters to work with other students, focusing on positive bystander behaviour	Middle School students, ages 11- 14, 1998-1999. In total 293.	- Self-report questionnaires - Peer nomination questionnaire to identify participant roles	Experimental and Control groups tested pre and post.	Differences between groups in that bullying significantly increased in the control group, but did not in the experimental group.

C. Interventions to tackle cases of bullying

Name of study	Nature of programme	Participants	Assessment method(s)	Design	Main outcomes
1. New South Wales, Australia (71) conducted 1995-1997	Applying the Method of Shared Concern with student collaboration	One secondary school. Students aged 12-17 years	Student questionnaires to assess behaviour and effectiveness of programme at the end	One pre and one post intervention test (no control group)	Reduction in bullying among the youngest students (Year 7) only. Older students registered an increase
2. The Oregon Study, USA (16). Conducted 1997-1998	The systematic use of positive and mild negative reinforcement to promote pro-social and discourage anti-social behaviour	Students in Grades 6,7 and 9 attending three Middle schools between 1997 and 1999.	Self-report questionnaires	Experimental and Control groups tested pre and post.	Significantly greater increases in safety in experimental group, but no differences in reported reductions in physical and verbal attacks
3. Bully Court Inquiry, England (22) Conducted 2000.	(i) Selection of student representatives to function in a Court to address bullying incidents (ii) Year 12 students to act as mentors for Year 7 students	Students at a large secondary school (> 1000) that had adopted the approach.	- Self-report questionnaires for students - Interviews of participants in the Courts	Evaluations based upon perceptions of the effectiveness of the Intervention	Strong support for the bully court system from both students and staff
4. Support Group Method, England (26) Conducted 1996-7	Application of the Support group Method of Maines and Robinson, whereby in the presence of supporters of the victim	Some 50 cases of bullying in primary schools in which the Support Group Method had been applied.	Interviews with participants in the application of the Method	Evaluations based on interviews relating to cases over a two year period	Some 80% of cases of bullying reported as having been immediately stopped; 14% stopped after a delay;

Table 1. (Continued)

Name of study	Nature of programme	Participants	Assessment method(s)	Design	Main outcomes
	bullies are presented with evidence of the harm experienced by a victim				6% victim reported continued bullying.
5. The Method of Shared Concern (Conducted 1991-1993), England (1)	Application of the Pikas method involving non-punitive interviews with suspected bullies, followed by interviews with all other students involved	Teachers at 14 schools (7 primary and 7 secondary) in Sheffield, England were trained in the use of the method	Interviews with teachers (N= 6) and students in cases in which the method was applied	Post intervention interviews	Five of the teachers reported that the method had reduced the frequency and severity of the bullying. Some 75% of students reported that the bullying had decreased.
6. The Method of Shared Concern (29,30). Australia. Conducted (2008-2009)	Application of the Method of Shared Concern (as above)	Application undertaken in Australia by trained practitioners on 17 occasions in selected schools	Interviews with the practitioners and participating students	Post intervention interviews	Interventions were reported as stopping or reducing the bullying in 15 of the 17 interventions.

D. Teacher training in classroom management

1. Teacher training Program, Norway (10) conducted 1992-94	In service training of teachers over 4 days in positive classroom management skills	Students (approx 1,200) from 9 primary schools, aged 6-8 years	Questions read out to students by teacher and explained when necessary.	The use of comparison groups from the previous year	Reductions in self reported bullying of 15% and being bullied, 18.7%
--	---	--	---	---	--

THE EFFECTIVENESS OF INTERVENTION PROGRAMS

An examination of results from the different studies indicates that there was in fact a very wide range of outcomes, with some claiming a reduction in bullying of around 50% and others showing little or no significant improvement. Unfortunately, the results obtained from evaluation studies do not enable us to decide which intervention program is the most effective. Notably, variations in outcome are evident for the most widely adopted anti-bullying program, the Olweus anti-bullying program. In successive interventions in Norway, Olweus (5) claimed reductions in reportedly being victimized of approximately 50%, 30%, 42% and 34%. In one evaluation of the program's effectiveness in another part of Norway, an actual increase in bullying was reported by Roland (33). In that study assessments of change were made over a different time period and using different research instruments. Evaluations of programs based upon the Olweus model outside Norway have produced quite small or inconsistent and, in some cases, non-significant outcomes; for example in USA (18), Belgium (20), Germany (21), Oregon, USA (34).

Several attempts have been to enable us to generalise about the likelihood of case interventions to reduce bullying actually working (35-41). The conclusions from such studies suggest that, at best, interventions have been modestly successful. Smith D, et al (36) examined 28 reports evaluating interventions. They concluded that among the most rigorously researched 86% of victimization effects were negligible or negative and the remaining 14% of reported effects were positive, albeit small. For self-reported bullying, 100% of the reported effects were negligible or negative. They added further: "Despite the limited empirical support for the effectiveness of antibullying programs, there is not sufficient evidence to conclude that these programs should be abandoned" (page 557). They opined that "only a cautious recommendation can be made that whole school anti-bullying be continued until they are evaluated further" (page 558). Smith P, et al (37) examined large scale studies conducted in England (two), Canada, Germany, USA, Norway (three), and in Belgium, Spain and Switzerland. They concluded that "the first implementation in Bergen, Norway, reported by Olweus, (5) has been the most successful, with subsequent attempts yielding much more modest outcomes – and at times even negative ones" (page 596). They added: "In our view, schools should continue with anti-bullying interventions" and "more research and evaluation is needed to maximise the effectiveness of such endeavours" (page 599). A further report (38) provided detailed reports from 14 contributors, who had conducted rigorous evaluations of antibullying interventions. A wide range of outcomes was reported - from over 50% reductions in bullying following the intervention to zero. On average, the reductions were modest in size, estimated at around 15%. This suggests that if there are six cases of school bullying occurring in a given year, at the completion of an average anti-bullying program one might expect about five cases of bullying to be still occurring ! Clearly at this level most interventions cannot guarantee substantial reductions.

Two further evaluations provide similar conclusions. In 2007 the Vreeman and Carroll (39) study examined 26 reports. They reported decreases in bullying following half of the interventions. They concluded: "Caution should be exercised in supposing that anti-bullying interventions invariably produce the intended results. Their review revealed that not all programs have proved effective" (page 87). Baldry and Farrington (40) examined sixteen major evaluations of programs to prevent school bullying, conducted in 11 different countries. Of

these, eight produced desirable results, two produced mixed results, four produced small or negligible effects, and two produced undesirable results. They concluded that the effectiveness of anti-bullying programs was not proven.' 'Nevertheless (they add) this pattern of results indicates that the findings of existing evaluations of anti-bullying programs are optimistic rather than pessimistic' (p 200). More recently Farrington and Ttofi (41) have reported a meta-analysis of results from 44 rigorously evaluated studies of the effectiveness of anti-bullying programs. They claimed that 19 of them were effective in reducing bullying and/or victimization (being bullied). On average, they concluded, reductions attributable to interventions were around 20%. These findings are consistent with a claim based on a study of changes in bullying prevalence among children over the last 10 years in 27 countries, indicating that modest reductions have occurred in most places(42).

One program that has recently become prominent in some countries, especially in the United States, is known as Bullying Prevention Positive Behaviour Support (43). It includes instruction provided by teachers on what constitutes unacceptable behaviour and how children who are targeted can best respond and also how cases of bullying can be handled by teachers through the use of positive reinforcement of more acceptable behaviour whenever it is observed. The effectiveness of this program has recently been supported in a large-scale study involving 12,344 students attending 37 elementary schools in Maryland, USA. Students in schools using the the program were subsequently significantly less likely to be involved in bully-victim problems than students in other (control) schools not using the program (44).

COMPARING THE EFFECTIVENESS OF WHOLE SCHOOL APPROACHES WITH CURRICULUM WORK ONLY

It should be noted that whole school approaches and the use of curriculum work are not mutually exclusive. Where curriculum work only is used to address bullying the effects may not be positive. Vreeman et al (39) report that 'of the 10 curriculum studies evaluated only 4 showed a decrease in bullying, and 3 of those 4 also showed no improvements in some populations (p 78). Those indicating no positive changes included class discussions of educational videotapes, cooperative group work and role-playing. Three studies involving the teaching of appropriate social skills, eg, promoting skills of listening, empathy and conflict resolution, showed no clear bullying reduction. In our own review, of the ones involving curriculum work with students (B1 to B4) three of them reported some reductions in bullying in some populations.

Some researchers are nevertheless positive about the potential role of anti-bullying content delivered through the curriculum, at the same time noting that much depends upon the integrity with which the programs are delivered in the 'messy and busy' world of the classroom. According to Durlak and Dupre "the magnitude of mean effect sizes are at least two to three times higher when programs are carefully implemented and free from serious implementation problems than when these circumstances are not present" (45, p.340).

Vreeman et al report favourable results for the employment of the whole school approach. In the ten studies that employed a whole school approach, seven revealed decreased bullying. Similar outcomes were indicated in our review of whole school interventions. Of the 21 listed in Table (Section A), 17 of them reported some significant reductions in bullying, although it

should be noted that of these, 8 achieved such success according to some but not all indices of bullying, or were successful with some but not all populations. In general, it may be concluded that where curriculum work focuses only upon the teaching of appropriate social skills, the outcomes have been less successful than when a whole school approach has been employed, though not all applications of a whole school approach have been successful.

REPORTED OUTCOMES FOR INTERVENTIONS WITH CASES OF SCHOOL BULLYING

Reports obtained from students who have been bullied and have gone to teachers for help suggest that teachers are successful in reducing or stopping bullying in some but not all cases. In England it was reported that among the students who told teachers that they were being bullied (about 40% of victims) approximately 50% reported that the bullying actually stopped or reduced (46). In Australia comparable results were reported and it was noted that the apparent success of teachers intervening so as to reduce the bullying depended largely on the age of the child. Around the age of 8 years most students reported that teacher intervention reduced the bullying. Students around 16 years of age who reported bullying to a teacher indicated that bullying did not usually reduce. Approximately 50% reported 'no change' and 10% that it got worse (47). Similar findings from student surveys conducted in the Netherlands (48) and the USA (49) have provided similar results. Somewhat more positive findings based upon teacher reports of outcomes after they have intervened suggest that interventions in England are successful in stopping or reducing the bullying in two out of three cases (50).

Some attempts have been made to assess the effects of particular kinds of interventions in cases of bullying. These include the use of direct sanctions, restorative practices, the Support Group Method and the Method of Shared Concern. (See full descriptions of these methods (51,52) It should be recognized that the cited studies that follow provide evidence regarding the effects that specified interventions can have *under particular conditions*. Relevant conditions may include (i) the nature of the proactive work that is or has been undertaken in a school, eg., the social skills or training provided for students as part of the curriculum (ii) the nature of the case of bullying to which the intervention method was applied, eg., whether physical or verbal and (ii) the age of the students involved. Hence reports of the effectiveness of interventions in cases need to take into account the conditions or circumstances in which the method was applied.

Reports from 25 schools in England based on cases (N = 274) for which direct sanctions have been applied indicate a success rate of 67%; that is bullying was stopped or reduced (50). A study in the United States in which negative sanctions were used (as well as positive reinforcement for desirable behaviour) suggests that the use of direct sanctions may not always result in overall reductions in bullying in a school (16). In that study although students reported that they felt safer there no reductions were reported by the students in either physical or verbal attacks.

Outcomes following the use of restorative practices or approaches have also been mixed. School reports in England (50) indicated that 73% of cases in which a restorative approach was used led to the bullying stopping or being reduced. However, other results from applications of the approach in England indicate that overall reductions in the prevalence of bullying in schools

commonly did not occur. In one study the effects of restorative practices in reducing bullying in schools were examined in 26 schools and compared with changes in control schools (53). No significant differences were found in 23 of the comparisons. There were 3 comparisons that favoured the restorative justice interventions. These were ones that were carried out over a longer period (3 years) possibly indicating that the method requires a long term commitment to be effective. In reporting their findings the authors pointed out that in about half the schools the staff knew little or nothing about restorative justice and those who did often had significant misconceptions.

By contrast, non-punitive approaches to bullying as reported in studies conducted in England have invariably been supportive of their effectiveness in preventing cases of bullying from continuing. School reports indicated that The Support Group Method successfully reduced bullying in 76% of cases (50). Further support for its effectiveness is evident in other reports (54,55,56). Similarly the Method of Shared Concern has been found to be effective in dealing with cases of bullying in England (1); supportive findings have also been reported in Australia (29,30). Despite these positive findings these methods are not widely employed. It was estimated that approximately 10% of schools in England use the Support Group Method and 5% use the Method of Shared Concern or Pikas Method.

It would appear from the above studies different methods of intervention in cases can be successful under some circumstances. Comparisons regarding their relative effectiveness have not at this stage enabled firm conclusions to be drawn. One difficulty in doing so lies in the likelihood that different methods may be employed by schools according to the nature of the bullying, for example, direct sanctions tend to be employed in more severe, physical or criminal forms of bullying (50). Allocating cases at random to different intervention methods can overcome this problem, as in a study reported in Finland (57) in which no significant differences in effectiveness was reported what were called confrontative and non confrontative methods of intervention. However, given the perceived appropriateness by schools of different methods for different cases, such findings lack ecological validity.

It is possible that reliance upon reinforcing desirable and undesirable social behavior differentially may depend upon how decisions to punish perpetrators of bullying are made. In the study conducted at a large secondary school in England where students accused of bullying were 'tried' by their peers the respondents who had taken part in the process were overwhelmingly positive about the outcomes (22). However, further research is needed to determine whether actual reductions in bullying did occur.

COUNTERING BULLYING THROUGH EFFECTIVE CLASS MANAGEMENT

Practically all interventions to reduce bullying have been direct in the sense that steps were taken to develop in students pro-social attitudes and behaviours that are incompatible with bullying; or alternatively, to tackle cases of bullying when they occur. So far there is one exception: teacher-training that seeks to improve the quality of teaching in order to bring about a positive classroom climate. The rationale for this approach is that when students are constructively engaged in their studies they are less likely to become involved in bullying. A Norwegian study (10) summarised on Table 1 (D), showed that bullying significantly decreased

as a result of teachers being trained in positive classroom management and subsequently teaching primary school students. Further research is needed to evaluate an extension of this work into secondary schools.

CYBERBULLYING

Thus far in this chapter we have not differentiated between programs or interventions that address cyber bullying as distinct from traditional forms of bullying. Based upon analyses of results from large samples of schoolchildren in the United States (N=65,000) and Norway (N = 9,000) it has been claimed that the prevalence of the former has been greatly overrated and in fact about 90% of cases of cyber bullying also involve traditional forms, eg, face to face verbal harassment at school. (58) Moreover, interventions that are effective in reducing traditional bullying also reduce cyberbullying (59). At the same time, there are novel features in cyberbullying that justify special attention. The fact that innovations in cyber technology are constantly occurring and pose new risks to users justifies the repeated updating of information about what difficulties students may encounter. It has been suggested that the use of student discussions and the sharing of information in classrooms using Quality Circles can help to educate children about the risks they may run in using cyber technology(60). However, it should be recognised that traditional and cyber bullying have this in common: they generally derive from tensions experienced in unsatisfactory relationships between people and can be most effectively addressed through the resolution of interpersonal problems, for example through the use of the Method of Shared Concern.

CONSIDERATIONS IN SELECTING A METHOD

Studies of the effectiveness of anti-bullying programs have rarely taken into account factors that almost certainly affect the outcomes of particular kinds of intervention. These include:

The nature of the bullying

Bullying clearly differs considerably in its nature. It is unreasonable to treat cases of extreme violence or repeated acts of bullying despite promises to stop in the same way as milder cases of bullying which have been in part provoked and then repented of. Arguably distinctions should be made between very severe cases that need to be handled in a strong disciplinary manner and those for which a counselling approach is more likely to be effective.

The age and maturity of children

The age and maturity of children involved in bullying. Interventions may have differential consequences for children of different age. Generally, it has been found that reductions in

bullying occur more readily among younger children (1,2,20) In a study of Italian students there were reductions in bullying following workshop presentations with older students on the harmfulness of bullying behaviour but not with younger ones (61). When an intervention requires a mature understanding of the psychological effects of bullying, it would appear to be more appropriately employed with older students. It has been suggested that 'authoritative suggestions' from teachers can be more influential with younger children than with adolescents for whom a process which encourages them to resolve conflicts by reasoning can be more effective (27).

Social and psychological characteristics of the children

There is evidence that programs may work more effectively with some groups than others. Bauer et al (34) reported that the Olweus anti-bullying program significantly reduced victimization among white but not black children. Some children require special treatment. For instance, children with asperger syndrome tend to become more involved in bully/victim problems than others because of a limited capacity to make reliable inferences from behavioral cues about what others are thinking and to interact appropriately. Consequently, interventions directed towards helping Asperger children to overcome relevant cognitive difficulties are desirable (62,63).

The adequacy of the research evidence

The adequacy of the research evidence supporting the efficacy of a program. Potential users of programs should take into account whether (i) the evaluative procedure made appropriate use of control or comparison groups, noting that reported levels of bullying are correlated with age (ii) whether the reported effects are statistically significant, that is, very unlikely to be due to chance factors (iii) whether positive outcomes have been consistently replicated.

The knowledge and interventive skills of teachers and counsellors

Interventions presuppose competence among those administering the process. This is especially true of technically complex methods, for example in conducting community conferences or in using the Method of Shared Concern

The readiness of the school to adopt a particular method or approach

Broad acceptance and understanding of an intervention method by members of a school staff and the school community is necessary for maximum effectiveness. For example, non-punitive methods of dealing with cases of bullying are unlikely to be successful without widespread support by the school.

THE IMPORTANCE OF IMPLEMENTATION

One of puzzling features of outcomes from anti-bullying programs is the radically different results that have been found for the same or similar intervention methods. One plausible suggestion is that outcomes are closely related to the thoroughness of program implementation. In one important study in Finland, the degree of implementation was positively correlated with actual reductions in reported bullying (2). Suggestions as to how implementation can be enhanced have included (i) raising awareness of school staff of the prevalence and harmfulness of bullying (ii) closely involving every staff member in the development of anti-bullying programs and (iii) school leadership exercising close control over the coordination of actions taken at all levels of the school community to address bullying.

CONCLUSION

We are at an early stage in developing and evaluating methods of reducing school bullying. Evidence is slowly accumulating that at least some interventions have been modestly successful; a few more so. Currently it is not known which is the best method. Generally, however, it is thought that a multidimensional approach is likely to be more effective, that is one combining both preventative and interventive methods in the context of a whole school approach. At the same time, it should be recognized that a range of other factors may be relevant to a program's effectiveness. These include the readiness of the school as a whole to accept and thoroughly implement an agreed policy. In addition, the severity and culpability of acts of bullying undertaken by children or groups of children of different ages may require different treatments. Health professionals and educators need to be aware of the alternative ways in which bullying may be countered and the circumstances in which they can be appropriately employed.

ABSTRACT

Bullying is a very toxic psychosocial stressor, associated with serious health problems and death, affecting both the victims and the bullies. This form of abuse or maltreatment occurs around the world and along the lifespan. Health professionals have the unique responsibility of promoting the development of community initiatives for the prevention of bullying and related health problems. This effort needs to include ongoing programs with elements of primary; second and tertiary prevention. These programs should be supported and monitored by a public health policy with a strategy aimed at developing a whole community awareness about bullying and the related health risks; prohibiting bullying and developing emotionally and physically safe environments, in schools and workplace settings. Public health policy needs to mandate the monitoring, detection and reporting of bullying incidents; provide guidance for school intervention and offer guidelines for medical consultation.

INTRODUCTION

For the past thirty years, a body of published research has described the nature, developmental and ecological aspects of bullying behaviors among children and adolescents, as well as adults in the workplace (1-5). Furthermore, there have been an increasing number of reports documenting a significant link between bullying and an array of serious health and safety risks, along the lifespan (6-49).

Adolescents who are involved in bullying incidents, as victims and/or perpetrators, are at a significantly higher risk than their peers, who are not involved in such incidents, in dying because of suicide, accidents or homicide (16,27,37,38,50).

It is therefore our responsibility, as health professionals, not only to intervene against bullying to better improve child health, but also to prevent death linked to bullying. To achieve these critical public health goals, we need to accomplish the following:

- raise the awareness of the entire community about the serious health risks associated with bullying, along the lifespan
- promote a whole community approach for the prevention of health risks linked to bullying

This paper has been prepared as a first step in reaching these objectives.

NATURE OF BULLYING

Dan Olweus (51,52), the pioneer in bullying research, first coined a definition of this problem: “a student is being bullied or victimized when he or she is exposed, repeatedly and

over time, to negative actions on the part of one or more students.” Furthermore he distinguished three forms of bullying behaviors: physical aggression (hitting, kicking, pushing); verbal harassment (threatening, teasing, calling names, making faces or dirty gestures) and indirect/relational mistreatment (ignoring or ostracizing somebody, spreading rumors).

The National Center of Education Statistics, for the purpose of collecting and using school crime, violence and incidence data, has defined bullying as “Repeated negative behaviors intended to frighten or cause discomfort. These may include, but are not limited to verbal or written threats or physical harm.” (57) In addition, it has defined hazing as “Committing an act or acts against a student or coercing a student to commit an act that creates risk of harm to a person in order to be initiated into a student organization or class.” (57)

The European Agency for Safety and Health at Work has identified bullying at the workplace as a “repeated, unreasonable behavior directed towards an employee, or group of employees, that creates a risk to health and safety.”(58)

We should include the action of “daring” somebody to perform a dangerous, illegal or inappropriate action, as a form of bullying. In this situation the victim, under the threat of losing approval, among the members of a group, carries out an action that may be inappropriate or dangerous. Therefore hazing could be regarded as a form of bullying.

EPIDEMIOLOGY

In 1998, 30% of US adolescents, reported moderate to frequent involvement in bullying behaviors, as bullies and/or as victims(53). In 2005, 12.5% of US adolescents indicated that they have been bullied, from once or twice a month to almost daily, in the previous 6 months (54). Almost 70% of these students were made fun of, subjected to rumors, made to do things they did not want to and were excluded from activities on purpose, while the rest of them experienced physical aggression such as being pushed, tripped, shoved, spit on, threatened with harm, or have property destroyed on purpose(55). 24% of students who were physically bullied, sustained physical injuries, including bruises or swelling; cuts, scratches, or scrapes; black eye or bloody nose; teeth chipped or knocked out; broken bones or internal injuries; knocked unconscious; or other injuries(56).

The prevalence of bullying gradually decreases in half, from grade 6 through 12 (56). Caucasian and Afro-American students were more likely than Hispanic and Other racial /ethnic groups in reporting bullying, with a ratio of 1.3 to 1. There were no significant differences by gender, in reporting incidents, but males were more likely than their female peers, in reporting injuries linked to bullying (31 vs. 18 percent) (56). This form of peer to peer abuse occurred with a 10 percent higher prevalence among students from rural and suburban schools than those attending urban schools, and 30 percent higher occurrence among students attending public schools than those in private ones.

The implementation of the World Health Organization Health Behavior in School-aged Children Survey(59), and the Global school-based student health survey(60), have provided evidence that bullying occurs among millions of adolescents living in at least 60 countries, around the world(61). Most of the studies of prevalence have focused the attention on adolescents, but it is important to recognize that it occurs along the lifespan, as early as in

kindergarten (62). A European Union survey (63), indicates that that 9% of workers in Europe, or 12 million people, reported being subject to bullying over a 12-month period in 2000.

A national telephone survey of US organizations, conducted by the National Institute for Occupational Safety and Health, showed that “24% of companies reported some degree of bullying occurring during the past year. In the most recent incident, the aggressor was typically an employee and the victim of bullying was also typically an employee” (64). It is evident that bullying occurs globally and along the lifespan.

SOCIO-ECOLOGICAL AND INDIVIDUAL PREDISPOSING FACTORS

The phenomenon of bullying “is encouraged and/or inhibited as a result of the complex relationships between the individual, family, peer group, school community and culture”(5). Ball et al (65) have reported the results of a research intended to demonstrate the influence of genetic and environmental influences in the development of bullies and victims roles. Their study, based on a nationally representative cohort of 1,116 families with 10-year-old twins, documented that “genetic factors accounted for 73% of the variation in victimization and 61% of the variation in bullying, with the remainder explained by environmental factors not shared between the twins.” This result is, however, challenged by the large variations in prevalence between countries, schools and school classes – and changes in prevalence over time. All these variations are unlikely to be explained by difference in genetic influences (24,61,66).

Previous exposure to victimization, at home, has been shown to be associated with participation in bullying at school as a bully, and or as a victim (67-70). Parental communication, social isolation, and classmate relationships were found to be similarly linked to bullying across racial/ethnic groups. (71)

We need to recognize the unique role of the “peer group power” as “powerful moderators of behavior in a school class” (72). Bystanders may reinforce bullies by “passively watching”, “actively modeling bullies” or “intervening on behalf of the victims” (73). Besides peer negative support, bullying behaviors can be significantly related to “normative beliefs approving of bullying” and “negative school climate” (74). The role of the whole community and culture, towards bullying, needs further exploration.

Bullying usually occurs in unsupervised areas, such as locker rooms, cafeteria, hallways, stairways, bathrooms, during recess, on school buses, or walking to and from school. It may also take place outside the school environment: after-school care, among neighborhood peers, summer camps, youth activities, among siblings (75) and more recently electronically, over cellular phones and the Internet (76-81).

Victimization among peers can be predisposed by multiple individual factors including: height (82,83); weight (84,85); abnormal dental features (86); impaired social interaction and non verbal learning disorders (87); cancer (88); cleft lip and palate (89); shyness (90);gender identity (91); wearing glasses 92); sexual orientation (93) ethnicity and religion (4).

DEVELOPMENTAL LINKS

There is a suggested link between “reported roles in school bullying, and victimization in the workplace” (95). The highest risk of workplace victimization was found among “those who

were both bullies and victims at school (bully/victims), followed by those who were only victims” (95). “Teachers who experienced bullying themselves when young are more likely to both bully students and experience bullying by students both in classrooms and outside the classroom” (96). There is a significant positive correlation between being a victim, a bully or a bully/victim, in elementary, high school and college, respectively (97). A link has been documented between development of social phobia, among adults, and their experiences of being teased or bullied during childhood (98)

ASSOCIATION OF BULLYING AND HEALTH RISKS

Bullying is a very serious psychosocial stressor, and as such it should be included in the Axis IV of the Diagnostic and Statistical Manual of Mental Disorders (99), or considered as a form of Mistreatment Syndrome (100). Involvement in bullying as a bully or as victim, along the life span, has been linked to a wide range of health problems, including frequent psychosomatic symptoms (13,14), depression (16,23,29,40,42), anxiety (9,23,98), inattention/hyperactivity (12), alcohol abuse (8,30), substance abuse (8), smoking (19), eating disorders (18,32,35), fibromyalgia (44), cardiovascular disease (46), accidental injuries (37,38) and suicide (16,27).

There have been 273 cases of death linked to bullying or hazing, published in English newspapers in the past 50 years (101). The American Medical Association has urged physicians to “be vigilant about signs and symptoms of bullying”, to be aware of its social and mental health correlates, “to screen for psychiatric co-morbidities”; “to counsel affected patients and their families on effective intervention programs and coping strategies”; and” to advocate for family, school, and community programs and services for victims and perpetrators of bullying” (102).

PREVENTION

The first bullying prevention and intervention strategy was developed by Olweus in 1983 (103), as a multilevel, multi-component school-based program. It was designed to prevent or reduce bullying among students age 6 to 15, by “restructuring the school climate”. Olweus reported a 50 percent reduction in the occurrence of bullying, over an eight month period of its implementation. This program became a paradigm for subsequent whole-school-based strategies, which were able to achieve some reduction in the prevalence of bullying, but their outcome was below the 50 percent reduction documented by Olweus (4,104). His program recommended a “zero tolerance” for bullying, that in itself is not effective, unless it is accompanied by a marked improvement in school climate. Such an atmosphere needs to foster peer support, mutual respect, better interaction, and enhanced sense among the victims of “security at school, greater self confidence, and a feeling of being liked and accepted by at least one or two fellow students”. Positive behavioral discipline should help the bullies to “have fewer aggressive reactions to the environment and assert themselves in more socially acceptable ways” (2).

A systematic review of school-based interventions to prevent bullying, including curriculums, “whole school interventions”, social skills groups, mentoring and social work support (105), has determined that “children’s bullying behaviors can be significantly reduced by well planned interventions”. It also observed that “the chance of success is greater if the intervention incorporates a whole-school based approach involving multiple disciplines and the whole school community”.

The costly relationship of bullying and health risks, and its occurrence along the lifespan, and in different community sectors, demands a three-tier response involving all segments of the community, including parents, students, school staff, professional, youth, civic, religious, labor and business organizations as well as government agencies.

WHOLE COMMUNITY THREE-TIER SYSTEM OF BULLYING PREVENTION

Primary Prevention: Includes all efforts to preclude bullying from occurring. At a minimum it should include the following components:

- Promotion of awareness about the nature of bullying, its serious health repercussions, the need to report incidents and ways to deal with them.

The concept of bullying should be clearly defined by providing an inclusive list of physical, verbal and relational types of this type of abuse. Misconceptions and myths need to be clarified. This information can be conveyed to students, starting in kindergarten, through health education curriculums that are adapted to developmental stages. All school personnel and parents should be informed through a series of workshops and/or town meetings. The media, fact sheets and the internet can be used to alert the community at large. Through the power of the pulpit, religious communities can be given details not only about the moral and ethical concerns about bullying, but also about its health and lethal consequences.

- Endorsement of a community rejection of bullying, for the preservation of ethical principles and human rights, as well as for the protection of public health and safety.

This endeavor can be established through a principle of zero tolerance to bullying, to be included in the policies of schools, aftercare activities, summer camps, religious, youth and sport activities, neighborhood playgrounds, prisons and workplace. Bullying between siblings should not be viewed as “normal sibling teasing or rivalry”, but must also be declared unacceptable behavior.

- Foster physical and emotional safe school, workplace and other community environments.

This effort can be achieved through the development of programs that enhance mutual respect, sensitivity and support of others with tolerance to diversity.

Secondary Prevention (Detection/Intervention): Involves the identification of bullying incidents and the intervention to prevent their reoccurrence, or the emergence of health, safety or educational consequences. This should be accomplished by:

- Close monitoring of possible bullying incidents by school personnel, parents or work supervisors.

In addition to the typical inquiries about their academic performance and other school or work activities, young people need to be periodically asked by their parents, school personnel and/or work supervisors whether anybody mistreats them, physically, verbally, or emotionally, and/or if they bully others.

- Medical detection, in every emergency or routine health evaluation or follow up visit.

Health care providers need to convey their concern about students mistreating each other, in school, aftercare programs, neighborhood, home (between siblings), or among people at workplace (in cases of adult patients). The concept of bullying should be explained by giving typical examples of physical, verbal or relational abuse. The patient should be asked if he or she has been bullied or bullied others, in the previous year. If the answer is positive, further inquiry needs to be made about the type of bullying, its frequency, location, and health and work/educational impact (physical symptoms, weight/appetite changes, sleeping or mood difficulties, anxiety, suicidal or homicidal ideas or attempts, injuries, absenteeism, decline of academic or work performance). The patient and parents should be asked whether the incident has been reported and if intervention has stopped it from recurring. If the patient is presenting medical or work/education problems linked to bullying he/she should be referred for treatment.

- Reporting incidents of bullying in school or work organizations should be part of a conscientious community public health attitude.

It should be construed as a pivotal tool to link the detection of bullying incidents with the appropriate interventions to preserve the physical and emotional wellbeing of both the victim and the perpetrator. It should not be regarded as an approach to get the bully in trouble, leading to punishment, because many victimizers suffer from similar health, safety and educational risks as the victim (106). There is a need to modify the cultural belief that reporting an incident of bullying is being a tattletale. There should be community encouragement and support for reports of bullying, for the wellbeing of all society members, with safeguards for those who report against any threat of retaliation or liability. The office of an Ombudsman or a hotline can provide support or guidance in reporting bullying incidents (107,108,109)

- Intervention

Upon receipt of a bullying incident report, school counselors should interview the bully and the victim separately, to ascertain whether they are experiencing associated morbidity, health/ safety or educational risks (physical/emotional symptoms, depressive episodes, psychosomatic symptoms, eating disorders, cigarette smoking, alcohol or other drug use or

abuse, runaway episodes, accidental injuries, suicidal or homicidal ideas or attempts, serious absenteeism or decline in academic performance). If the bully and/or the victim are experiencing morbidity associated with the involvement in bullying they should be referred for medical and/or psychiatric intervention. Otherwise steps can be implemented, at the school level, to prevent the bully from repeating further incidents and for the victim to receive appropriate support and relief.

It would be helpful for the bully to receive individual or group counseling to understand the hurt that was inflicted, and develop respect, empathy, tolerance and sensitivity. Positive reinforcement should be strongly considered, while disciplinary or punitive measures with bullies who may have suffered from previous victimization, may lead to possible side effects like depression, suicide, and/or further physical or verbal aggression. The understanding and acceptance by the bully, of the harm that has been caused, should be followed by a process of “restorative justice”, by apologizing to the victim and establishing a positive future interaction (110).

The role of peer support to the victim should be beneficial to alleviate the sense of isolation, and to minimize the impact of the victimization.

A program was developed to promote the positive role of bystanders in order to discourage bullying behavior when they witness it (111). In this context, we should be cautious of potential side effects of this intervention, either by direct retaliation against the bystander, or indirect effects of bullying on witnesses of these episodes.

Ongoing monitoring must be implemented to ensure that the episodes of further bullying by the same perpetrator do not reoccur, in which case the perpetrator should be referred for tertiary prevention.

Tertiary Prevention: Consists of all medical interventions to prevent the reoccurrence of bullying incidents which failed to be stopped by school/organizational strategies and the treatment of bullying related health, safety and educational problems, affecting the bully and or the victim.

- Completion of full evaluation

A comprehensive psycho biosocial assessment should review the genetic and environmental precursors that may facilitate the development of psychiatric conditions that precede or are triggered by the participation in bullying behaviors (9, 10, 20, 112-114).

- Mental health treatment intervention

There is reported experience documenting the efficacy of Brief Strategic Family Therapy, in the treatment of adolescents who are bullies (115-117), as well as Social Skills Group Intervention to help victims of bullying (118). The role of Brief Cognitive Behavioral Intervention should be explored in the treatment of victims of bullying, following the experience established by this form of treatment with survivors of other forms of victimization (119,120). Psychopharmacological treatment needs to be considered for the stabilization of the regulatory Central Nervous System systems of impulsivity, mood, aggression, alarm system (anxiety), self esteem, thinking, sleeping and appetite that may have been disrupted, prior to or as a consequence of the victimization.

- Monitoring

On going monitoring should be established to rule out suicidal or homicidal ideation or plans, a recurrence in bullying participation, and/or exposure to new types of victimization.

PUBLIC HEALTH POLICY

There is a need for the implementation of local and national legislation that delineates the concept of bullying and its link to public health risks, prohibits bullying, requires implementation of prevention programs and provides the necessary funding (121). It should also required the participation of public health officials to promote community understanding of the association of bullying with health risks, provide community guidelines for detection and intervention and periodically monitor the prevalence of bullying and its health correlates. It is also recommended that all medical examiners' reviews of adolescent deaths due to suicide, homicide or injuries should include an inquiry about history of bullying.

CONCLUSION

There is an urgent public health need for health practitioners to spearhead initiatives for the prevention of bullying and related health risks. These programs should include all segments of the community in supporting the implementation of a three tier anti-bullying prevention strategy model. Its vital objective is to avert bullying related deaths, due to suicide, homicide or injuries.

Chapter 87

TOWARDS A DETECTION OF BULLYING RELATED MORBIDITY

Jorge Srabstein*, MD

Clinic for Health Problems Related to Bullying, Children's National Medical Center,
Montgomery County Outpatient Center, Rockville, Maryland, US

ABSTRACT

Physicians are being confronted with the responsibility of detecting bullying related health and safety risks in different clinical settings. Recommendations are being made on the basis of research evidence of a significant link of bullying with a wide array of health and safety problems; the author's clinical routine practice of ascertaining patients' participation in bullying and a recommended role for clinical detection of bullying within a whole-community base strategy for its prevention. Recommendations: There is a need to develop a standardized strategy for detection of bullying related morbidity which could be utilized in all clinical settings with sensitivity to developmental and cultural differences in the understanding of what is meant by bullying. Such an approach should ascertain the exposure of different types of bullying across social settings and its symptomatic repercussions. Its results should be used for clinical decisions to procure intervention and treatment, within a three tier bullying prevention strategy. Conclusions: The present chapter is the result of a work in progress which will contribute to efforts to develop a clinical practice guideline providing a standardized strategy for the detection and intervention of bullying related health and safety problems, within a primary or specialty pediatric setting. Bullying is at the intersection of many health and safety risks and health practitioners are challenged with the critical public health responsibility of their detection, prevention and intervention. It would be expected that the recommendations contained in this article should facilitate the development of strategies to fulfill such a responsibility.

INTRODUCTION

There is evolving research-based evidence documenting a range of health and safety problems affecting young people who are being bullied and or bully others (1-27). They are particularly at risk of suicidal attempts (11,12,14,15,19) and suffering from frequent sleeping difficulties, depression, anxiety, irritability, and physical symptoms (8,9,21,24,25).

The wide scope of bullying related morbidity poses a significant challenge to health practitioners not only to intervene against bullying to improve child health but also to prevent death link to this serious form of maltreatment. This responsibility can be accomplished within a whole community three system of bullying prevention (28). Such a strategy includes efforts to preclude bullying from occurring (primary prevention), by promoting whole community awareness about the nature and toxicity of bullying and through the implementation of programs to foster physical and emotional safety in schools and other social environments. Bullying behaviors not averted by a first level of prevention can be stop from recurring through a standard system of detection followed by school intervention through a reporting procedure (secondary prevention). Detection is also pivotal for the recognition of bullying related morbidity which may require treatment (tertiary prevention).

The responsibility of health professionals in the prevention, detection of and treatment of bullying related morbidity has been emphasized in policies and position statements of medical organizations (29-32), as well as in editorials (33, 34) and articles (28,35-37).

Recommendations have been made for children and adolescents to be screened for involvement in bullying and associated symptoms, at routine clinical visits or periodical medical examinations (28,35-37) and approaches for this clinical detection have been suggested (36,37).

So far, there is no published clinical practice guideline providing a standardized strategy for the detection and intervention of bullying related health and safety problems, within a primary or specialty pediatric setting. The purpose of this article is to put forward recommendations for objectives, elements and ways to conduct such a clinical inquiry.

METHODS

The recommendations made in this article have been developed on the basis of:

- 1) Evidence about morbidity associated with participation in bullying, based on non clinical population of young people surveyed on cross sectional and longitudinal national studies (1-27).
- 2) The author's clinical routine practice of ascertaining patients' participation in bullying and their experience with associated health or safety problems.
- 3) A recommended role for health practitioners' detection of bullying and related morbidity within a whole-community three-tier prevention strategy (28).

RECOMMENDATIONS

Objectives

- 1) Detect patients ongoing and recent (last two months), exposure to being bullied;
- 2) Ascertain health and safety problems among patients who are exposed to ongoing or recent bullying incidents;
- 3) Inquire about bullying and related health and safety problems among all patients being seen by child and adolescent primary care and specialty health practitioners, in outpatient, emergency and inpatient settings;
- 4) Raise awareness, among all patients and their parents, about the nature and toxicity of bullying, across different social settings, and ways to prevent it within a whole-community effort;
- 5) Help to avert ongoing bullying behaviors by promoting school intervention. It should insure counseling of those who bully others and support to the victim;
- 6) Foster a reporting strategy, that is comfortable to patient and parents, to facilitate school intervention to halt ongoing bullying;
- 8) Facilitate psychiatric treatment of health and safety problems related to bullying.

Elements and ways

- 1) Explain that questions about bullying are being asked on a routine basis to all patients to insure their safety. This explanation should help to insure that the patient does not feel “singled out”. Furthermore it helps to raise awareness about the serious medical concerns linked to this form of mistreatment;
- 2) Provide a developmental and cultural sensitive understanding about the concept and nature of what is being understood as bullying (38);
- 3) Ask whether the patient is currently and or in the previous two months, being bullied;
- 4) Inquire details among those who are being bullied (where does it happen, type of bullying, frequency, people involved as perpetrators or victims);
- 5) Develop a standard questionnaire that could be used to screen all patients (see appendix 1) or utilize such a questionnaire as a framework to conduct a face to face anamnesis (see appendix 2);
- 6) Promote the value of reporting incidents of bullying as a way to insure students’ safety.
- 7) Help to dispel the notion that reporting of bullying is being “a snitch” to get the perpetrator in trouble or punished, but rather to insure school intervention to counsel the perpetrator; protect the victim and stop further victimization;
- 8) Support the student and parent’s reporting of bullying with a medical statement if required (see appendix 3)
- 9) Recommend intervention steps (clinical algorithm) on the basis of information gathered through the questionnaire or clinical anamnesis (Appendix 4). Patients who are being bullied require school intervention to halt further incidents. Consideration of mental health treatment should be considered for those with related morbidity.

DISCUSSION

The present paper is the result of a work in progress which will contribute to efforts to develop a clinical practice guideline for the prevention, detection and treatment of bullying related morbidity,

The screening tools offered in this paper have not yet been applied on an adequate size sample in different clinical settings and therefore we could not draw conclusions about its efficacy.

It can be argued that one of its limitations could be its inability to gather cross-informant agreement from teachers and peers, beyond information obtained from student and parents. Such additional information would be logistically impossible to obtain from a brief clinical screening tool, which is only geared towards a triage strategy to decide the need for intervention and treatment, and not for epidemiological research objectives. The global prevalence of bullying requires that its clinical detection should be sensitive to cultural differences in the understanding of what is being considered as bullying.

The intention of this report is not to offer a final screening tool for detection of bullying related morbidity but rather to contribute with preliminary recommendations for how to conduct such an assessment and guidelines on how to utilize its results for clinical decisions for school intervention and medical treatment.

CONCLUSION

Bullying is at the intersection of many health and safety risks and health practitioners are challenged with the critical public health responsibility of their detection, prevention and intervention. It would be expected that the recommendations contained in this article should facilitate the development of strategies to fulfill such a responsibility.

APPENDIX 1

CHECKING FOR BULLYING (Prototype of a questionnaire)

Dear patients,

Doctors and nurses are concerned about children and adolescents getting physically or emotionally sick when they are being bullied. That is the reason why we will be asking you some questions about bullying and health problems.

First we need to explain that somebody is being bullied if he or she is being hurt, harmed, made fun of, bothered, mistreated, hassled, provoked, insulted, or not accepted by one or more people.

You are being bullied if any one of these things happens to you:

Hit; kicked; pushed, slapped; choked; punched; threatened; made fun of; teased; called names, or have your belongings stolen, hidden, destroyed or tossed around.

You are also being bullied if rumors are being spread about you; if you are being ignored or not accepted as a friend or if you are dared or pushed to do something dangerous or inappropriate, in exchange of being liked or accepted as a friend.

Bullying can happen anywhere: in school, walking to and from school, in the school bus; at home; in the neighborhood; after school care; in summer camp; in dating relationships; over the Internet or cellular phones and at work.

QUESTIONS ABOUT YOU BEING BULLIED

1) Are you being bullied, in the last 2 months?

YES ____

NO ____

If you answered **NO** you have completed this questionnaire and we **thank you!!!**

If you answered **YES**, please also complete the following questions:

2) Where have you been bullied? Please check one or more:

At home

In school

Riding the school bus

In the neighborhood Walking to and from school

After school activities

Extracurricular activities (Music or ballet lessons, organized sports, summer camp, scouting)

Email, Face book, Text message

Dating relations

Workplace

3) How have you been bullied? Please check one or more:

Hit

Kicked

Pushed

Slapped

Choked Punched

Threatened with physical harm

Made fun of

Name calling

Teased

Being ignored or not accepted

Rumors being spread about you

Your belongings being stolen, hidden, destroyed or tossed around

Dared or pushed to do something inappropriate or dangerous in exchange of something

4) How often are you being bullied? Please check one

Less than once a

once a week

Several times

Almost every

week

a week

day

5) By whom are you being bullied? Please circle one or more

Sibling

Student/students in your school

Neighbor

Friend

Teacher

Coach

Counselor

Girlfriend/Boyfriend

Parent

QUESTIONS ABOUT PROBLEMS RELATED TO BEING BULLIED

1) In the last 2 months, have you suffered more than once a week, from any of these physical or emotional problems? Please circle:

HEADACHES	YES	NO
STOMACHACHES	YES	NO
DIZZINESS	YES	NO
BACKACHES	YES	NO
FEELING SAD OR DEPRESSED	YES	NO
FEELING ANGRY OR IRRITABLE	YES	NO
DIFFICULTIES IN SLEEPING	YES	NO
FEELING ANXIOUS, NERVOUS OR WORRIED	YES	NO
2) In the last 2 months have you have any of these problems? Please circle		
THOUGHTS OF HURTING YOURSELF	YES	NO
THOUGHTS OF HURTING SOMEBODY ELSE	YES	NO
TRYING TO HURT OR KILL YOURSELF	YES	NO
TRYING TO HURT OR KILL SOMEBODY ELSE	YES	NO
RUNNING AWAY	YES	NO
FEELING AFRAID OF GOING TO SCHOOL	YES	NO
BEING FREQUENTLY ABSENT FROM SCHOOL	YES	NO
DROP IN YOUR SCHOOL GRADES	YES	NO
GETTING HURT IN PHYSICAL FIGHTS	YES	NO
CARRYING A WEAPON (Knife, gun, rifle, broken bottle. Baseball bat)	YES	NO
SMOKING CIGARETTES DAILY	YES	NO
HAVING SEVERAL DRINKS IN A FEW HOURS	YES	NO
USING DRUGS	YES	NO

APPENDIX 2.

HYPOTHETICAL CLINICAL VIGNETTE WITH PHYSICIAN-PATIENT DIALOGUE ABOUT BULLYING

Jane is 14 year old female being seen by her primary care physician because of “not feeling well, feeling tired and missing school.”

For the past 2 weeks the patient has been absent from school almost every other day, because of tiredness in the morning with intermittent headaches and dizziness. She has not experienced nausea, vomiting, lack of appetite, fever or any other symptoms. Her physical examination and laboratory data were normal.

During the anamnesis the patient and physician entertained the following dialogue:

- Physician: I am very concerned about young people getting hurt by being bullied or mistreated. For this reason, I ask all my patients about their experience with bullying...I am sure that you know about this...
- Patient: (assents)...
- Physician: Can you tell me what the word bullying means to you?
- Patient: Well...it means when somebody pushes you, or they are mean to you by making fun...
- Physician: That's right; there are many different types of bullying. Do you mind if I tell you about all the different forms of bullying, so we are both talking about the same thing?
- Patient: Yeah...go ahead...
- Physician: Well... it could be when somebody hurts you physically by pushing, kicking, hitting, slapping you, or threatening to hurt you. It can also be with words, by making fun of you, teasing you, calling you bad names, spreading rumors about you, telling you that you are not accepted in a group, game, conversation or you cannot be their friends...So, bullying can be one or more of those things...
- Patient: (Looks upset)... Yes, it happens to me...
- Physician: I am sorry to hear about that... how have you been bullied?
- Patient: One classmate keeps calling me dirty names and making fun of my teeth and my tone of voice...She also stole my cell phone.
- Physician: It happens inside the school?
- Patient: Yes, at lunch time, or in the locker room.
- Physician: When did it start?
- Patient: Since school started, about 6 months ago...
- Physician: How does it make you feel?
- Patient: Depressed, angry and feeling that I want to hurt her.
- Physician: Have you told somebody or asked for help?
- Patient: If you report it, they call you a snitch, and they don't do anything. Actually, once I complained to the counselor. She brought both of us into her office so we could “solve the problem.” She blamed me for being angry. Actually there is no

conflict to resolve between this other student and me. I just want her to leave me alone.

- Physician: Does it happen in other places?
- Patient: Yes...the same kid that bothers me started a campaign in Face book and by emails spreading rumors about my morals. She calls me a “fat slut.”
- Physician: How often do you feel depressed and very irritable or angry?
- Patient: Almost every day when I come back from school
- Physician: Have you ever felt that you wanted to die or hurt yourself?
- Patient: Yeah... It happens a lot
- Physician: Have you had these thoughts today or in the last few days?
- Patient: No...
- Physician: Have you ever tried to hurt yourself?
- Patient: Yeah...three months ago I took a bunch of Tylenol
- Physician: Did you tell anybody?
- Patient: No... I just vomited it...
- Physician: If you ever feel like hurting yourself, would you please ask your parents help, and make sure that they consult with the Hospital Emergency Department...
- Patient: OK... I will
- Physician: I need to share this situation with your parents.
- Patient: OK... If you think that they will help me...
- Physician: What time do you fall asleep at night?
- Patient: I cannot fall asleep until two in the morning, and then I have nightmares that wake me up.
- Physician: We need to have the school help you to stop the bullying
- Patient: They do nothing...or they don't know how to stop it...
- Physician: You and your parents can report it and ask for support
- Patient: I don't want to be call a snitch...I am afraid.
- I can help you with a medical note asking the counselor to help the kid that is bullying you understand of the harm that she causing you and stop mistreating you... She should not be punished, but helped...Reporting problems of bullying is not to get people in trouble, but to make sure that everybody is safe....
- Well, let me think and talk with my parents....

APPENDIX 3.

MEDICAL STATEMENT ADVOCATING FOR SCHOOL INTERVENTION

Jane is a 14 year old patient under my medical care. She has a history of frequent depression, easy frustration and anger, frequent headaches, difficulties in sleeping, thoughts of hurting herself, decline in academic grades and frequent absenteeism.

For several months she has been subjected, in school, to frequent mockery about her weight and moral reputation. She has been made fun of her dental features and tone of voice, have her belongings stolen and rumors about her, spread over the Internet.

Bullying is associated with serious health problems and death, affecting those who are victimized and/or those who bully others, as well as those who are bystanders.

Jane's rights to a physical and emotional safe school working environment should be immediately protected. It is strongly recommended that those who bully her should be sensitized/ counseled about the serious health risks linked to bullying and advised to stop this behavior.

If their bullying behavior continues in spite of school intervention, it is advisable that they should be referred to sources of health care to help ascertain and stabilize their biological/psychological and or social difficulties which may be leading to bullying incidents.

We will provide to Jane the necessary medical care to alleviate her physical and emotional symptoms associated with bullying. In the meantime, it is extremely important for her treatment that the school protects from further bullying incidents.

At present she is not a risk to self or others and should be able to return to regular school activities.

Chapter 88

COPING STRATEGIES OF SECONDARY SCHOOL STUDENTS EXPERIENCING BULLYING: FREQUENCY, TYPE OF BULLYING AND PSYCHOSOCIAL DIFFICULTIES

I. Bibou-Nakou¹ and A. Markos²

¹Department of Primary Education, Aristotle University of Thessaloniki, Greece

²Department of Primary Education, Democritus University of Thrace, Greece

ABSTRACT

In this study we examined adolescents' perspectives on what interventions they consider to be effective in order to a) overcome the difficulties of being bullied by peers and b) to stop a student being bullied. Our main aim was to investigate the extent to which students classed as bullies, victims, bully/victims, and not involved would differ in their coping strategies in response to different types of bullying, and the relationship between bullying and psychosocial well-being as measured by the Strengths and Difficulties Questionnaire (Goodman, 1997). Participants were 502 students aged 12-14 years old attending 4 high schools from different geographical areas. They were asked to fill in a self-report revised version of the Olweus Bully/Victim Questionnaire (Olweus, 1993) and in the SDQ self-report version. Results showed that students' psychosocial well-being differed in relation to the bully status type and their coping strategies. The frequency of victimization did not differentiate the strategies of the students, whereas students experiencing more than 3 types of bullying stated that they were significantly more afraid of being bullied again in comparison to those experiencing only one type of bullying. Overall, adolescents' perceptions of effective ways to make bullying stop fit well into the categories that were formed to represent the suggestions made by the majority of researchers.

Keywords: Bullying in secondary school students, coping strategies, psychosocial well being

1. INTRODUCTION

Although little research existed as regards bullying behaviour in schools prior to the 1990s, the knowledge base in the European Union member states concerning the incidence, prevalence and typology of this phenomenon has been considerably expanded (Minton, & O'Moore, 2004). The relatively newly founded research traditions concerning bullying in Europe have been shaped by many factors such as: the operation of the various educational systems, the development of national anti-bullying programs, the enforcement of anti-bullying legislation and other governmental measures to counteract bullying, problems of definition of the phenomenon as well as methodological variations regarding its research. According to the first extensive study on bullying in Greece, 14.7% of a sample of 8-12 year-old students were involved in bullying as victims, 6.2% as bullies and 4.8% as bully/victims at least once a week (Houndoumadi, & Pateraki, 2001). According to the WHO Bullying behavior amongst 13-year-olds (Currie, et al 2004), secondary school students were asked to answer whether or not they were engaged in bullying in the last school term. 76.8% of Greek students answered that they had not; 18.9% stated that they engaged in bullying sometimes, and a small percentage (4.4%) answered that this kind of involvement was once a week or more often. Although, there has been little systematic research on bullying at a national level, the prevalence of bullying involvement among 11- to 15-year-old students was investigated in a relatively recent nationwide survey. A representative sample of 2200 children along with their teachers and parents took part (Deliyianni-Kouimtzi, 2005). In this study the percentage of students attending secondary education who reported being bullied "sometimes" or "more often" was 9.1%, and the proportion who reported bullying others "sometimes" or "more often" was 10%. Overall, 30% of secondary students in the same study stated that they had been bullied at least once.

When the academic and professional debate first started in this field among educationalists, psychologists and social workers, bullied children were conceptualized as "passive victims" who could not react to what had been happening to them. However, recent data show that children who experience bullying have their own coping strategies and their own perspectives on what happens to them (Bibou-Nakou, Tsiantis, Asimopoulos, & Chatzilambou., 2012). This realization led to a conviction that research in this field must involve children directly, as well as the adults who care for and work with them. It also means that as users of services, children require interventions tailored to their level of understanding, their age or stage of development, their particular viewpoint, and their specific circumstances. According to Frisé, & Holmqvist, (2009), there are strong arguments for investigating the students' suggestions for how to stop bullying, as this could be worthwhile for research on anti-bullying interventions. First of all, students are active agents in the social setting of school where bullying occurs. They face daily experiences of various bullying situations, and actively negotiate ways to manage them effectively. Consequently, their views and suggestions should form part of effective anti-bullying strategies. Moreover, in the majority of bullying situations, most students are involved as observers since most bullying occurs when school staff and other adults are not around (Rigby, 1996). Furthermore, the new sociology of childhood (James & Prout, 1997; Qvortrup, 1994) and the children's rights movement (Alderson, 2000; Freeman & Veerman, 1992) have stressed the need for children to be actively involved in the selection, evaluation and decision making of psychological interventions that concern them.

While some countries have made significant efforts towards addressing bullying, related work in Greece is just beginning. Thus, the present paper aims at extending previous findings on the prevalence of bullying in Greek schools and on the bullying experiences of secondary school students. In addition, it focuses on students' own suggestions on how to stop bullying and the association of coping strategies to their psychological well being¹. In other words, the present study attempts to identify the prevalence of bullying among high school students, to evaluate whether involvement in bullying as bullies, victims or bully-victims is associated with psychosocial difficulties and to understand how bullying profile groups differ from one another with respect to the coping strategies adopted.

Children's coping has been discussed in the literature in its immediate and long-term perspective and classified as a) outward-looking (talk, find a safe place, seek help and get adults to take responsibility, be active and involved in finding solutions) *versus* b) inward-looking (cry, fear, secrecy, concealment, dissociating from it as though it's not happening). Other classifications discuss coping in terms of approach versus avoidance strategies or problem-focused versus emotion-focused coping Kristensen, & Smith, 2003. Lazarus, & Folkman, 1984).

Bullying in secondary schools has been less researched in comparison to elementary school (O' Moore, & Minton, 2004; Pellegrini & Bartini, 2000). According to some researchers, the transition from elementary to secondary education is often associated with a decrease in severity during early adolescence (Sweeting, Young, West, & Der, 2006. Sullivan, Cleary, & Sullivan, 2003). On the other hand, there is evidence to suggest that adolescent students tend to employ new ways of relating with their peer groups, some of which are recognized as aggressive behaviours (Pellegrini, 2002). Recent studies have examined students' perceptions of how victims should cope with bullying situations (Kanetsuna, Smith, & Motiys, 2006; Smith, et al., 2004).

Bullying has been linked with children's social and psychological difficulties (Alikasifoglu, Erginoz, Ercan, Uysal, & Albayarak-Kaymak, 2007. Snyder, Broker, Patrick, Snyder, Schrepferman, & Stoolmiller, 2003. Sweeting, et al, 2006), some of which can be long-lasting and persist into adulthood (Cowie, Dawn, & Sharp, 2005. Esteves, Musitu, & Herrero, 2005. Finkelhor, Turner, & Ormrod, 2006). For example, bullied students-in comparison to the not involved ones- present significantly more emotional problems (Delfabbro, et al., 2006. Olweus, 1993) such as depression (Sweeting, Young, West, & Der, 2006) or anxiety (Due, et al., 2005). The bullies may also present serious antisocial problems, broader difficulties in social adjustment over time (Rigby, 1996. Smith & Brain, 2000) and increased risk of deviance (Ahmed, & Braithwaite, 2004. Nadeem, & Graham, 2005). Further, bully/victims have been found to experience the worst outcomes in psychosocial assessments such as peer acceptance, positive social functioning, and emotional difficulties (Georgiou & Stavrinides, 2008; Haynie, Nansel, Eitel, et al., 2001).

¹ The present study forms part of a bigger international project under the title "Needs Assessment and Awareness Raising Program for Bullying in Schools. It was funded by the EE (Daphne Initiative Project Grant Agreement: JLS/DAP/2005-1/040/YC30-CE-0062092/00-78, under the scientific leadership of Professor I. Tsiantis, Child Psychiatrist, Association for the Psychosocial health of Children and Adolescents, Athens.

2. METHOD

2.1. Participants and Procedure

A total of 502 students from 3 classes in four different high schools of Thessaloniki, Greece (population circa 1,200,000) took part in the study. The schools were from the various geographical areas being randomly selected from the city's list of public schools. Of the 502 participants, 163 students (32.5%) were in the first year of high school; 150 (29.9%) were in the second year and 180 (35.9%) attended the 3rd year. 52.9% were girls ($n = 257$) and 47.1% were boys ($n = 229$). Reported ethnicity was 88.6% Greeks ($n = 445$), and 11.4% ($n = 57$) from other ethnic communities (mainly from Albania (3.6%), and former Soviet Union countries (3.4%).

Permission to conduct the research was granted by the Ministry of Education. Students took the survey as part of an assessment to measure the level of bullying behaviours in the first three years of high school, which is junior high school (or *Gymnasio*) in the Greek education system. All students who participated provided informed consent and filled out the questionnaires anonymously. The survey was administered during a regular classroom period and students were monitored by the first researcher who administered the questionnaires and responded to students' questions. Data from the four schools were combined for analysis after preliminary testing indicated that participants were reasonably matched on the demographic variables of gender and age and in terms of socio-economic status.

In terms of parental education, the majority of both parents had graduated University studies (fathers, 39.8%; mothers, 43.8%), followed by those who had completed the six years of secondary education (fathers, 22.3%; mothers, 25.9%). A very small percentage had finished the three-years of compulsory secondary education (fathers, 10.2%; mothers, 9.6%).

2.2. Instruments

The most common instruments used in the research on bullying are questionnaires for students or teachers and less often for parents (O'Moore, & Minton, 2004). In general the questionnaires for students can be classified into two categories a) those that identify bullies and victims through self-report and b) those based on peer nomination procedures. The most commonly-used self-report is probably the Olweus student questionnaire (Olweus, 1996). The Olweus instrument presents a wide view of the problem, even though it is difficult to score as well as lacking the social and affective structure of the whole-class group and the teachers' support of the students². Several adaptations have been made in many countries. In Greece, Deliyianni (2005) made the first adaptation for a large study of 2200 students from all levels of schooling (primary, secondary schools, representative samples of both students, & teachers). In the present study, the above mentioned adaptation was used along with the Strengths and Difficulties Questionnaire (Goodman, 1997) which is a screening questionnaire on students'

² This is the reason that we added extra questionnaires to get information about teacher and classmate support as evaluated by the students themselves. The study contained a number of other psychological, behavioral, and relational measures, as this was part of a larger research project; only the parts of the research that are relevant to the current chapter, however, are reported in the following sections.

psychosocial well-being that has been adapted to the Greek context (Bibou, Stogiannidou, & Kioseoglou, 2000). Specifically, participants completed a self-reported instrument, which included the following sections:

2.2.1. Bullying Information

The Olweus Bully/Victim Questionnaire, used in a national study (Deliyianni-Kouimtzis, 2005), divides experiences of bullying into: *physical bullying*, being hit, kicked, pushed, shoved around; *attack on property*, having had money or other things taken away from one, or damaged; *verbal bullying*, being called mean and hurtful names or being threatened (further distinguishing between *racist* and *non-racist* forms of verbal bullying; sexual harassment); *indirect bullying*, having other children tell lies, spread rumors, to try to make others dislike one; and *social exclusion*, students purposely not including other children in activities, excluding one from their group of friends, or completely ignoring one. The 16 items included were 8 items about the children as victims and the same 8 items about the children as bullies. The students filled in the questionnaire in a 5 Likert-scale (from 1= "never", 2="1-2 times", 3="2-3 times per month", 4="once a week" and 5="several times a week").

2.2.2. Coping with bullying

The students were asked to answer the following question: "Overall, how do you react when you experience one or more of the above mentioned situations (the different types of bullying, e.g., calling names, hitting, threats, etc)?" The 9 items selected as ways of coping ways in a dichotomous way (though the students being asked to tick more than one options) were grouped as follows: Seeking Social Support, "Get help from a friend", "Talk to the teacher or another adult about it"; Problem-Solving, "I tried to take precautions"; Distancing, "I would ignore it", "I would try to avoid the situation"; Internalizing, "I would burst into tears"; Avoidance, "I would run away, I would hide", and "I would avoid the situation"; Retaliation, "I would take revenge". The scale was addressed only to students being defined as victims.

2.2.3. Disclosure of Bullying

The bullied students were then asked to state on a 2-point form (1=yes and 2=no, being able to tick more than one options) whether or not they have talked about the bullying experience to a number of significant people that form part of their social support. ("Have you told anyone that you have been bullied at school in the past couple of months?"). The options presented were as follows: I have not told anyone; my class (home room) teacher; another adult at school (a different teacher, the principal/ headmaster, etc); my parent(s)/guardian(s); brother(s) or sister(s); friend (s) and somebody else. On the same scale, the students were asked whether or not they receive support from the school staff (either a teacher or somebody else at the school). The question was as follows: "How often do the teachers or other adults at school try to put a stop to it when a student is being bullied at school?" They were asked to pick up one option and fill in a range from "1"=almost never, to 5="almost always". In addition, they were asked to answer the following question: "How often do other students at school try to put a stop to it when a student is being bullied at school?" with the same range of options. Lastly, the students answered the following question "Has any adult at home contacted the school to try to stop your being bullied at school in the last couple of months?" with a range of: "1"= no,

they haven't contacted the school"; "2"= yes, they have contacted the school once and "3"= yes, they have contacted the school several times.

2.2.4. Reactions towards a Bullied Classmate

All the students had to answer the following question: "How do you usually react if you see or understand that a student your age is being bullied by other students?". The answers were: I take part in the bullying; I don't do anything and I think the bullying is Ok; I don't do anything, and I think the bullying is fun; I just watch what goes on; I don't do anything, but I think I ought to help the bullied student; I try to help the bullied student in some way.

A question then addressed to all students was about the fear of being bullied ("How often are you afraid of being bullied by other students at your school?" and the range of answers on a 6-point scale were from "1"=never to "6"= almost always.

Definition of the Bullying Profile (Bully Victim Status Type)

Students who responded that at least one of the eight types of bullying had happened to them "two or three times a month" or more, or that at least three of the five types of bullying had happened to them "only once or twice", were classed as *victims*. Students who replied that they had bullied one or more student(s) "two or three times a month" in at least one way, or that they had bullied one or more student(s) "only once or twice" in at least three different ways, were classed as *bullies*. Students who scored this high on both the victimization and the bullying measures were classed as *bully/victims*. Students who did not score this high on any of the measures were classed as *not involved* (Kristensen, and Smith, 2003). We thus classified students into four bullying profile groups as victims, bullies, bully-victims and not involved. The analyses investigating the variables of the study by the number of ways in which students experienced a bullying behaviour, have adopted the above mentioned criteria of bullying profile group. The rest of the analyses were carried out either in the total sample of the students or as otherwise stated.

2.2.5. Psychosocial Well Being

The Strengths and Difficulties Questionnaire (SDQ) is a brief self-report behavioural screening questionnaire that exists in several versions (for parents, for teachers, for students aged 11 to 16) to meet the needs of researchers, clinicians and educationalists. The SDQ includes 5 scales with 5 items each: 1) emotional symptoms 2) conduct problems, 3) hyperactivity/inattention, 4) peer relationship problems and 5) prosocial behaviour. The students completed the questionnaire. The SDQ generates a total difficulties score based on the 20 items of the first four scales. It has been widely used as a screening test, for epidemiological and research reasons and for clinical assessment (Goodman, 1997). The version for youths was used in the present study, which was found to have satisfactory psychometric properties in Greek adolescents (Giannakopoulos, Tzavara, Dimitrakaki, Kolaitis, et al. 2009).

Cronbach's alpha coefficients were calculated for the total difficulties scores and for the five subscales using the data in this study and are displayed in Table 1. Cronbach's alphas were sufficient (i.e., $\geq .60$) for the total difficulties score and the emotional symptoms and prosocial behaviour subscales. However, alphas for hyperactivity-inattention (.40), conduct problems (.54) and peer problems (.55) fell below acceptable limits. The low Cronbach's alpha for these subscales is problematic and has been reported in previous studies as well. The reason might

be the limited number of response categories (Van Roy, Veestra, & Clench-Aas et al. 2008) or the fact that reverse items seem to confound the SDQ factors (Riso, Salcuni, & Raudino, 2010).

Table 1. Internal consistency and descriptive statistics of Strengths and Difficulties Questionnaire

Areas of psychosocial difficulties	Difficulties (%)	Moderate difficulties (%)	No (%)	Cronbach's alpha
Prosocial behavior	11.8	9.5	78.7	.68
Hyperactivity and attention deficit	13.9	12.1	74.0	.40
Emotional disturbance	7.6	5.0	87.4	.68
Conduct disorder	10.2	9.6	80.2	.54
Peer relation difficulties	18.9	56.8	24.3	.55
Total score difficulties	10.7	22.8	66.5	.70

2.3. Statistical Analysis

Bivariate relationships between categorical variables were examined using the chi-square test with Monte Carlo simulation or Fisher's exact test, where appropriate. Monte Carlo approximations for p -values were obtained using 10,000 permutation tests. Group differences were assessed by one-way ANOVA followed by Scheffé's multiple comparisons test with effect size measured by partial eta squared (η_p^2). Where the distributional assumptions of ANOVA were not met, nonparametric Kruskal-Wallis tests followed by Dunn's multiple comparisons test with effect size measured by eta squared were employed. Effect sizes were interpreted according to Cohen's (1988) guidelines. Statistical significance was set at 0.05 and all analyses were conducted using the IBM Statistics SPSS software (version 19.0).

3. RESULTS

3.1. Bullying Information

According to the definition of the bully-victim status type given previously, the majority of children were not involved in bullying (58.9%, $n = 287$), although a substantial number were victims (16.4%, $n = 112$), and smaller numbers were bully/victims (12.7%, $n = 62$) and bullies (8.2%, $n = 26$). Fifteen children (3.0%) had missing data and were not included in the analysis.

Bully-victim status type differences by gender are also shown in Table 2. More girls than boys tended not to be involved in bullying events (58.9% vs 41.1%), virtually the same number of boys and girls reported being victims (50.9% vs 49.1%), and a larger number of boys than girls tended to report being bullies (61.5% vs 38.5%) or both bullies and victims (62.9% vs 37.1%). An overall chi-square test revealed that the relationship between gender and bully-victim status type differences was significant ($\chi^2(3) = 13.43$, $V = 0.166$, $p < 0.001$)

Table 2. Distribution of children across gender in different bully–victim status types

			Victim	Bully	Bully/Victim	Not Involved	Total
Sex	Girl	<i>n</i>	55	10	23	169	257
		%	49.1%	38.5%	37.1%	58.9%	52.8%
	Boy	<i>n</i>	57	16	39	118	229
		%	50.9%	61.5%	62.9%	41.1%	47.2%
Total		<i>n</i>	112	26	62	287	487
		%	100.0%	100.0%	100.0%	100.0%	100.0%

Table 3 shows bully–victim status type differences by school year. Examining school year differences, on average the younger students tended to be victims more than the older sample (29.6% vs. 18.8%), were bullies slightly less than the older sample (4.3% vs. 6.2%), and tended to be bully/victims less than the older sample (8.6% vs. 17.6%). However, an overall chi-square test showed that the relationship between school year and bully–victim status type was not statistically significant.

Table 3. Distribution of children across school year in different bully–victim status types

			Victim	Bully	Bully/Victim	Not Involved	Total
School year	A	<i>n</i>	48	7	14	93	162
		%	29.6	4.3	8.6	57.4	100.0
	B	<i>n</i>	31	8	17	93	149
		%	20.8	5.4	11.4	62.4	100.0
	C	<i>n</i>	33	11	31	101	176
		%	18.8	6.2	17.6	57.4	100.0
Total		<i>n</i>	112	26	62	287	487
		%	23.0	5.3	12.7	58.9	100.0

3.2. Frequency of Victimization

The frequencies of victims who reported that they had been bullied in one, two and three or more ways are summarized in Table 4. A small proportion (16.1%) reported that they were bullied in three or more ways, while the majority of those bullied (60.7%) reported only one way of being bullied. Chi-squared tests did not show any significant differences across gender and school year.

Table 4. Number of ways students experienced bullying

	<i>n</i>	%
Bullied one-way	68	60.7
Bullied two ways	26	23.2
Bullies three or more ways	18	16.1
Total (of Victims)	112	100.0

3.3. Forms of Bullying across Gender, School Year and Frequency of Victimization

In terms of the most commonly used forms of bullying, the most likely ways of being bullied reported by students who indicated that they had only been bullied in one way was being sexually harassed (32.35%), called names (25.0%) and rumors being spread about them (17.6%) (see Table 5).

Table 5. Forms of bullying experienced by students reporting being bullied in only one way

Called Names	Socially excluded	Hit	Spread rumors	Stolen things	Threatened	Insulted	Sexually harassed	Total
17 (25.0%)	6 (8.8%)	2 (2.9%)	12 (17.6%)	5 (7.35%)	3 (4.4%)	1 (1.5%)	22 (32.35%)	68 (100.0%)

Approximately two in three students (60.7%, $n = 305$) reported that they had been bullied in at least one of the eight ways, 2 or 3 times per month. Of those, 68.2% reported "calling names", 49.2% "sexual harassment" and 48.8% "spreading rumors". Males were more likely to report being called names (Fisher's Exact test $p < 0.001$), being hit (Fisher's Exact test $p = 0.033$), being threatened (Fisher's Exact test $p = 0.001$) and being insulted due to origin (Fisher's Exact test $p < 0.001$) than females (see Table 6)³.

Table 6. Forms of bullying experienced by students across gender

Forms of bullying	Female ($n = 150$)		Male ($n=155$)		Total ($n = 305$)	
	<i>N</i>	%	<i>n</i>	%	<i>n</i>	%
Calling names, insulting**	87	58.0	121	78.1	208	68.2
Social exclusion	45	30.0	44	28.4	89	29.2
Hitting*	15	10.0	26	16.8	41	13.4

Sexual harassment	76	29.6	74	31.7	150	49.2

**Between gender, $p < 0.001$

* Between gender, $p < 0.05$

In terms of the different forms of bullying across the school year, no statistically significant differences were found (see Table 7), despite the fact that the 3rd year students were more likely to report most form of bullying than the 1st and 2nd year students.

³ The sum of percentages from the Table 6 till the Table 14 is greater than 100%; this is due to the fact that the students could tick more than one of the options offered (e.g in Table 16, some students had experienced more than one way of being bullied and they stated it).

Table 7. Forms of bullying experienced by students across school year

Forms of bullying	A (n = 106)		B (n = 84)		C (n = 115)		Total (n = 305)	
	n	%	n	%	n	%	n	%
Calling names, insulting	69	65.1	64	76.2	75	65.2	208	68.2
Social exclusion	30	28.3	23	27.4	36	31.3	89	29.2
Hitting	12	11.3	9	10.7	20	17.4	41	13.4
Spreading rumors	46	43.4	42	50.0	61	53.0	149	48.9
Stealing things	16	15.1	14	16.7	23	20.0	53	17.4
Threatening to cause fear	22	20.8	13	15.5	22	19.1	57	18.7
Insulting in terms of origin	14	13.2	7	8.3	20	17.4	41	13.4
Sexual harassment	48	45.3	38	45.2	64	55.7	150	49.2

3.4. Coping Strategies across Frequency of Victimization, Gender, and School Year

We next investigated whether there were differences in terms of the students' coping and the frequency of victimization (Table 8). Chi square analysis, investigating victims' coping by frequency of bullying did not present any statistically significant differences. The data, however, indicated that those students who had been bullied in 3 ways or more, stated that they would use the strategy of ignoring and taking revenge to a lesser degree (44,4% & 11,1% respectively), but they would use the strategies of informing the teacher and running away/hiding to a higher degree 27.8% & 22,2% respectively). These differences were not statistically significant and include coping strategies of approach, avoidance or distancing and escaping as well.

Table 8. Coping behaviour in the case of being bullied by frequency of victimization

Coping behaviour in the case of being bullied by frequency of victimization	One (n=68)		Two (n=26)		Three or more (n=18)		Total (n=112)	
	n	%	n	%	n	%	n	%
I would tell a teacher or some other adult at school	10	14.7	2	7.7	5	27.8	17	15.2
I would ignore it	38	55.9	18	69.2	8	44.4	64	57.1
I tried to take precautions	14	20.6	10	38.5	5	27.8	29	25.9
I would burst into tears	3	4.4	4	15.4	3	16.7	10	8.9
I would run away, I would hide	4	5.9	3	11.5	4	22.2	11	9.8
I would seek help from friends	13	19.1	5	19.2	4	22.2	22	19.6
I would take revenge	10	14.7	5	19.2	2	11.1	17	15.2
I would plead with them to stop	5	7.4	6	23.1	1	5.6	12	10.7
I would avoid getting into the situation	25	36.8	14	53.8	7	38.9	46	41.1

Overall, the most preferred coping strategies were ignoring the fact (56.1%, $n = 171$), avoiding getting into the situation (32.1%, $n = 98$), taking revenge (26.9%, $n = 82$) and taking precautions (21.3%, $n = 65$). The least preferred ways of managing bullying were bursting into tears (6.9%, $n = 21$) and running away (5.9%, $n = 18$).

When coping was examined in relation to gender (Table 9), statistically significantly more girls would seek help from friends than boys (Fisher's exact test, $p < 0.001$). No other differences were found in coping strategies in relation to the students' gender.

Table 9. Coping behaviour in the case of being bullied by gender

Coping behaviour in the case of being bullied by gender	Female (n = 150)		Male (n = 155)		Total (n = 305)	
	n	%	n	%	n	%
I would tell a teacher or some other adult at school	15	10.0	14	9.0	29	9.5
I would ignore it	87	58.0	84	54.2	171	56.1
I was trying to take precautions	34	22.7	31	20.0	65	21.3

I would run away, I would hide	6	4.0	12	7.7	18	5.9
I would seek help from friends**	36	24.0	14	9.0	50	16.4
I would take revenge	34	26.7	48	30.9	82	26.9
I would plead them to stop	15	10.0	12	7.7	27	8.8
I would avoid getting into the situation	46	30.1	52	33.5	98	32.1

** $p < 0.001$

On the other hand, no statistically significant differences were found in the bullied students' coping strategies by school year (see Table 10). A more careful analysis of the students' answers reveals a non-significant tendency for the 3rd year students to be resigned to informing the school teachers (6.1%) and to increasing their attempts in taking precautions (25.2%).

Table 10. Coping behaviour in the case of being bullied by school year

Coping behaviour in the case of being bullied by school year	A (n = 106)		B (n = 84)		C (n = 115)		Total (n = 305)	
	n	%	n	%	n	%	n	%
I would tell a teacher or some other adult at school	11	10.4	11	13.1	7	6.1	29	9.5
I would ignore it	61	57.5	49	58.3	61	53.0	171	56.1
I tried to take precautions	20	18.9	16	19.0	29	25.2	65	21.3
I would burst into tears	6	5.7	11	13.1	4	3.5	21	6.9
I would run away, I would hide	9	8.5	3	3.6	6	5.2	18	5.9
I would seek help from friends	19	17.9	10	11.9	21	18.3	50	16.4

I would plead with them to stop	7	6.6	8	9.5	12	10.4	27	8.9
I would avoid getting into the situation	32	30.2	26	31.0	40	34.8	98	32.1

3.5. Disclosure

We then examined disclosure in the case of being bullied by the frequency of victimization (Table 11). No significant differences were found, although students who had been bullied in

3 or more ways tended to talk about their bullying experiences with their teacher more in comparison to the two other groups (33.3%). In addition, they tended to address to the incident with their friends to a lower degree (38.9%), in comparison to students who has been bullied in one or two ways (64.7% and 65.4% respectively).

Table 11. Disclosure among victims by frequency of victimization

Disclosure in the case of being bullied by frequency of victimization	One (n=68)		Two (n=26)		Three or More (n=18)		Total (n=112)	
	n	%	n	%	n	%	n	%
I have not told anyone	12	17.6	5	19.2	3	16.7	20	17.9
My class (home room) teacher	9	13.2	6	23.1	6	33.3	21	18.8
Another adult at school	4	5.9	0	0.0	2	11.1	6	5.4
My parent(s)/guardian(s)	21	30.9	7	26.9	4	22.2	32	28.6
Brother(s) or sister(s)	13	19.1	6	23.1	2	11.1	21	18.8
Friend(s)	44	64.7	17	65.4	7	38.9	68	60.7

Although, overall, the majority of bullied students would disclose their experience to some other person, one in four students-most likely male- would not tell anyone about it. Friends were by far students' first choice (58.4%), followed by no one (24.6%) and parents (24.3%). A small percentage of students who had been bullied stated that they would tell their teacher about their experiences (14.4%) (see Total, Table 12).

As presented in Table 12, in comparison to girls, boys are more likely to not share their experiences with anyone ($p < 0.05$). Girls, on the other hand, in comparison to boys, are more likely to share their experiences with friends.

Table 12. Disclosure in the case of being bullied by gender

Disclosure in the case of being bullied by gender	Female (n=150)		Male (n=155)		Total (n=305)	
	n	%	n	%	n	%
I have not told anyone*	28	18.7	47	30.3	75	24.6
My class (home room) teacher	16	10.7	28	18.1	44	14.4
Another adult at school	4	2.7	8	5.2	13	4.3
My parent(s)/guardian(s)	40	26.7	34	21.9	74	24.3
Brother(s) or sister(s)	22	14.7	22	14.2	44	14.4
Friend(s)**	102	68.0	76	49.0	178	58.4

* $p < 0.05$

** $p < 0.001$

When disclosure was examined in relation to the school year, it was found that significantly more students attending the 3rd year would tell a friend or a sibling about being bullied (Table 13).

Table 13. Disclosure in the case of being bullied by school year

Disclosure in the case of being bullied by school year	A (n=106)		B (n=84)		C (n=115)		Total (n=305)	
	n	%	n	%	n	%	n	%
I have not told anyone	34	32.1	21	25.0	20	17.4	75	24.6
My class (home room) teacher	15	14.2	15	17.9	14	12.2	44	14.4
Another adult at school	5	4.7	3	3.6	5	4.3	13	4.3
My parent(s)/guardian(s)	33	31.1	17	20.2	24	20.9	74	24.3
Brother(s) or sister(s)*	12	11.3	11	13.1	21	18.3	44	14.4
Friend(s)**	53	50.0	51	60.7	74	64.3	178	58.4

* $p < 0.05$ ** $p < 0.001$ **3.5.1. Disclosure across Bullying Profile Group**

Students were asked to respond to the following question: Have you told anyone that you have been bullied at school in the past couple of months? Table 14 shows that 32.3% of bully/victims had not shared their bullying experiences with anyone, in comparison to 17.9% of students who had been bullied. Both groups would disclose the bullying incident to their class teacher almost to the same degree (19.4% and 18.8% respectively). However, whereas 28.6% of the bullied students would trust their parents to disclose their experience to, only 19.4% of the bully/victims would do so.

Table 14. Have you told anyone that you have been bullied or that you have bullied another student (s) at school in the past couple of months?

Coping behaviour	Have you told anyone that you have been bullied (Victim, n = 112)		Have you told anyone that you have been bullied (Bully/Victim, n = 62)	
	n	%	n	%
I have not told anyone	20	17.9	20	32.3
My class (home room) teacher	21	18.8	21	19.4
Another adult at school	6	5.4	6	6.5
My parent(s)/guardian(s)	32	28.6	32	19.4
Brother(s) or sister(s)	21	18.8	21	11.3
Friend(s)	68	60.7	68	59.7

The following tables (Tables 15a,b and 16a,b) present useful data about the bullied students and the bully/victims' views regarding the interventions by teachers, their peer group, or family members. Students who had been bullied stated that 33.6% of teachers and 25.4% of peers attempt to put an end to the bullying often or almost always, whereas the comparative percentages for bully/victims were 26.3% and 19.7% respectively.

Table 15a. Overall, how often do you think the others have tried to put a stop to it when a student is being bullied at school? (Victim)

	Teachers or other adults		Other students	
	<i>n</i>	%	<i>n</i>	%

Table 16b. Has any adult at home contacted the school to try to stop your being bullied at school? (Bully/Victim)

Has any adult at home contacted the school to try to stop your being bullied	<i>n</i>	%
No, they haven't contacted the school	43	72.9
Yes, they have contacted the school once	10	16.9
Yes, they have contacted the school several times	6	10.2
Total	59	100.0

The following tables (Tables 17 and 18) refer to the bullies' views regarding their behaviour at school and how it is recognized by the teacher or a family member. According to the students, it appears that both teachers (78.3%) and parents (60.9%) do not talk with a student who bullies others about this behaviour.

Table 17. Has your class teacher talked with you about your bullying other students at school in the past couple of months? (Bully)

	<i>n</i>	%
No, they haven't talked with me about it	18	78.3
Yes, they have talked with me about it once	5	21.7
Yes, they have talked with me about it several times	0	0.0
Total	23	100.0

Table 18. Has any adult at home talked with you about bullying other students at school in the past couple of months? (Bully)

	<i>n</i>	%
No, they haven't talked with me about it	14	60.9
Yes, they have talked with me about it once	7	30.4
Yes, they have talked with me about it several times	2	8.7
Total	23	100.0

3.6. Fear of Being Bullied

In relation to the fear of being bullied and the bully status type, one-way ANOVA indicated significant differences in fear levels between groups ($F(3,295) = 6.64, p < 0.001$). Bullied students and bully/victims reported significantly higher levels of fear than students who were not involved in a bullying incident (Scheffé's post hoc test $p < 0.05$) (Table 19).

Table 19. Bullying profile group and fear of being bullied

Status type	Mean (SD)
Victim ($n = 104$)	2.16 (1.17)
Bully ($n = 13$)	1.85 (0.80)
Bully/Victim ($n = 60$)	2.43 (1.38)
Not Involved ($n = 119$)	1.71 (0.90)
Total ($n = 296$)	2.02 (1.14)

Table 20. Fear of victimization in relation to the frequency of victimization

Frequency of Victimization	Mean (SD)
One way	1.90 (0.96)
Two ways	2.32 (1.38)
Three ways or more	2.83 (1.29)
Total ($n = 104$)	2.16 (1.17)

Furthermore, there were significant differences between the relationship of the fear of being bullied and the frequency of victimization (One-way ANOVA $F(2,101) = 5.025, p = 0.029$, Scheffé's post hoc test $p < 0.05$). In other words, those students who had been bullied in 3 or more different ways were significantly more afraid of being bullied by other students, in comparison to the bullied students who had experienced only one way (Table 20).

3.7. Reactions towards a Bullied Classmate

No significant differences were found in relation to gender and students' reactions once they realised that a student at their school was being bullied. In addition, no differences were found in the students' reactions and the school year. Overall, the majority of the students stated that they would try to help a classmate who was being bullied (51.9%), or they believed that they ought to do so (24.5%). Only 9% of the students stated that they would just watch and a very small percentage found that bullying is ok (5.7%) or fun (3.7%).

On the other hand, as can be seen in the following Table 21, there were significant differences between students' reactions and their bully status type ($\chi^2(18) = 93.39, p < 0.001$). An inspection of Table 21 reveals that the majority of victims (61.5%) reported that they try to help the bullied student in one way or another, whereas a significant percentage of bullies (20.8%) stated that they take part in the bullying. In comparison to the other status types, bully/victims mostly reported that they just watch what goes on (21.1%), don't do anything and they think bullying is OK (15.8%) or fun (14.0%). Finally, students not involved in bullying stated that they try to help the bullied student (55.1%), and that even though they might not do anything, they think they ought to help the bullied student (28.3%) (Table 21).

Table 21. Reactions towards a bullied classmate by bully status type

Reactions		Victim	Bully	Bully/Victim	Not Involved	Total
1. I take part in bullying	<i>n</i>	3	5	3	5	15
	%	2.9	20.8	5.3	1.5	3.3
2. I am forced in a way to take part in bullying	<i>n</i>	2	0	2	5	9
	%	1.9	0.0	3.5	1.8	2.0
3. I don't do anything, but I think bullying is OK	<i>n</i>	5	3	9	9	26
	%	4.8	12.5	15.8	3.3	5.7
4 I don't do anything, but I think bullying is fun	<i>n</i>	5	1	8	3	17
	%	4.8	4.2	14.0	1.1	3.7
5. I just watch what goes on	<i>n</i>	3	2	12	24	41
	%	2.9	8.3	21.1	8.0	9.0
6. I don't do anything, but I think I ought to help the bullied student	<i>n</i>	22	5	8	77	112
	%	21.2	20.8	14.0	28.3	24.5
7. I try to help the bullied student in one way or another	<i>n</i>	64	8	15	150	237
	%	61.5	33.3	26.3	55.1	51.9
Total	<i>n</i>	104	24	57	272	457
	%	100.0	100.0	100.0	100.0	100.0

3.8. Psychosocial Difficulties

A series of One-Way ANOVA's were conducted with the bully-victim status type as an independent variable and the SDQ subscale scores and the total difficulties score as dependent variables. The differences were significant in all cases (see Table 22). Overall, bully/victims scored significantly higher in the total difficulties score and its subscales than the students not involved in bullying. All effect sizes are small to moderate in size, with conduct problems, peer problems and total difficulties demonstrating the largest effect sizes of all measured.

Table 22. Bully-victim status type by SDQ

	Victim	Bully	Bully/ Victim	Not Involved	Total	ANOVA	Sig. Differences
PROS	7.44 (1.93)	6.52 (2.93)	6.43 (2.12)	7.34 (2.21)	7.21 (2.21)	$F(3, 441) = 3.73$, $p = 0.011$, $\eta_p^2 = 0.025$	1 vs 3, 3 vs 4

Prosocial Behaviour (PROS), Hyperactivity–Inattention (HYPER), Emotional Symptoms (EMO), Conduct Problems (COND), Peer Problems (PEER), Values are Means (SD).

Next, the Kruskal-Wallis test followed by Dunn's multiple comparison test was performed, with the bully-victim status type as an independent variable and the SDQ subscale scores and the total scale score as dependent variables. Significant differences of medium effect size were found in relation to bullied students' reactions and SDQ (see Table 23). Specifically, the more a student stated that she/he would partake in bullying a classmate, the fewer were his/her positive social skills in comparison to students who stated that they believed they ought to help or did try to help a classmate who was being bullied. In addition, students who stated that bullying is a normal experience or that it is a way of having fun had more conduct behavioural difficulties, in comparison to those who stated that they would try to stand up for a bullied student. Nevertheless, students' psychosocial functioning was not associated with feeling fear of being victimized.

4. DISCUSSION

In this study, we aimed to investigate reported coping strategies used by students, in relation to gender, age, and bully–victim status. We also looked for possible differences in coping in response to multiple bullying and for the association of bullying experience and coping strategies with the students' psychological well being.

Table 23. Students' reactions towards a bullied classmate by SDQ

	PROS	HYPER	EMO	COND	PEER	TDS
1 I take part in bullying	4.60 (2.41)	4.13 (1.81)	2.92 (2.29)	3.25 (1.91)	3.92 (2.10)	13.40 (6.20)
2. I am forced in a way to take part in bullying	5.44 (1.51)	5.00 (1.87)	2.11 (1.69)	2.66 (1.87)	4.78 (1.30)	14.55 (5.32)
3. I don't do anything, but I think bullying is OK	6.83 (1.74)	4.52 (1.81)	3.48 (2.50)	3.27 (2.33)	4.36 (1.49)	15.75 (5.73)
4 I don't do anything, but I think bullying is fun	6.53 (2.29)	4.73 (1.49)	3.40 (2.64)	3.53 (2.19)	4.37 (1.31)	15.21 (4.40)

In terms of the prevalence of bullying, the present study showed that 16.4% of the students were identified as victims, 12.7% of them as bully/victims and 8.2% as bullies. These percentages are similar to the findings by Alikasifoglou et al., (2007), although higher compared to other national studies. For example, in her study in the same geographical area, Sapouna (2008) found that 6.1% of the students were identified as victims, 1.1% as bully/victims and 5.8% as bullies. The cut-off point of "2-3 times a month" was used as prevalence estimation of bullying in that study. This difference in the prevalence of bullying may be due to the broader identification criterion of involvement in bullying in the present study ("two or three times a month" or more, or at least three of the five types of bullying experienced "only once or twice"). Furthermore, a United Nations international survey found that in Greece the percentage of students (ages 11-15) that stated being bullied within the last two months in Greece was 26% for both females and males. In another study, Kokkinos and Panayiotou (2004) from a sample of 12-15 year old Greek Cypriots found 21.5% to be victims, 15.25% bully/victims and 8.4% bullies. It is quite obvious from the literature that there is a lack of consensus internationally on the frequency of bullying; this might be due to various methodological issues (such as operational definitions of the problem, measurements used, participating informants, quantitative and qualitative data, etc).

39.3% of the bullied students in the present study reported having been bullied in more than one ways, a finding that is similar to the study by Skrzypiek, Slee, Murray-Harvey & Pereira (2011) of 452 students in the same age group.

In line with findings from almost all countries (Junoven, & Graham, 2001; Rigby, 1996), name calling was the most common type of bullying experienced by students, followed by sexual harassment and rumors being spread about them (Sapouna, 2008). Being hit was reported by 3.06% of the bullied students, and attack on property (stealing things) was reported by 8.67%. Skrzypiek et al., (2011) point out the association between "being called names" and feeling unsafe at school and emphasize that this form of victimization should not be overlooked or discounted as insignificant.

Boys are more likely to be physically victimized (Olweus, 1993; Houndoumadi, & Pateraki, 2001), and threatened or insulted in terms of origin than girls. However, there was no difference between boys and girls as to the likelihood of experiencing any of the other types of bullying (Skrzypiek, et al., 2011).

4.1 Frequency of Bullying and Coping

The present study has not shown significant associations between frequency of bullying as measured by students being exposed to one, two or three and more forms of bullying, and ways of coping; this is in line with Hunter, Boyle and Warden's (2004) but contrary to some other studies (Hunter & Boyle, 2004; Houndoumadi & Pateraki, 2001; Naylor, Cowie, & Del Rey, 2001) where, in most of the last studies frequency was measured either as a Likert scale ranging from "everyday" to "never" or as a measurement of the duration of bullying (e.g., more than 6 months). In addition, the data of the present study indicate that while there were some differences between the three bullied groups in the coping strategies used, these were not statistically significant. For example, fewer students being bullied in three ways or more stated that they would use the strategies to ignore and take revenge, while a greater number of students would inform the teacher and run away/hide. Hunter, Boyle, and Warden (2004) found that as the experience of negative emotion from being bullied increases, bullied students are more likely to seek help from an adult.

4.2. Coping and Bullying Profile Group

In the present study, "ignoring the bullying" (56.1%) and "avoiding getting into the situation" (32.1%) were the most used coping strategies among all students, followed by "taking revenge" (26.9%), "taking precautions" (21.3%), and "asking help from a friend" (16.4%). The least preferred coping strategies were "telling a teacher or some other adult at school" (9.5%), "pleading with the bullies to stop" (8.8%), "bursting into tears" (6.9%) and "running away or hiding" (5.9%). Similar findings were reported by Smith et al., (2001) in England investigating coping strategies used by 10- to 14-year-old victims of bullying (more or less the same age group used in our study as well). We would like to point out that 27.4% of the bullied students stated that revenge was their preferred choice. The general evidence is that "fighting back" or "counter-aggression" are not very successful strategies (Kochenderfer-Ladd, 2004; Salmivalli, et al., 1996).

Informing the teachers was the third choice of students being bullied in three or more ways (27.8%), whereas it was one of the least preferred strategies among the students experiencing one or two ways of bullying. Among the studies that focus on students' perceptions of how victims should cope with bullying situations (Kanetsuma, Smith, & Morita, 2006; Naylor, Cowie & Rey, 2001) Crothers, Kolbert, & Barker (2006) found, that, overall, teachers' engagement is an effective strategy according to students' perceptions of effectiveness. This is provided that teachers intervene in bullying situations quickly and effectively and help the person being bullied in practical ways.

In the present study, internalizing or passive ways of coping were least used among students. Although there is evidence that internalizing behaviours such as withdrawing and crying are more prevalent in children who have been bullied when compared to those who have not been bullied (Olweus, 1993; Schwartz et al., 1993). this finding was not confirmed in our study. 16.3% of the bullied students chose revenge; retaliation and counter-aggression were associated with psychological maladjustment and the perpetuation of victimization in many studies (Kochenderfer-Ladd, 2004; Kochenderfer-Ladd, & Skinner, 2002; Mahady-Wilton, Craig, & Pepler et al., 2000).

4.3. Gender and Age in Relation to Coping

In terms of gender distribution across bully-victim status types, our findings are in line with previous work. The most obvious gender difference is that more boys tend to be involved in acts of bullying than girls (Deliyianni, 2005; Rigby, 1996). In terms of gender differences and coping strategies, girls reported "seeking help from friends" significantly more, and are more likely to share their bullying experience with a friend than boys. A significantly higher number of male students stated that they had not told anyone about it. Similar findings were obtained by Smith et al. (2001). This gender difference may be attributable to a range of factors, including gender role socialization. Boys are socialized to be independent, whereas girls are socialized to seek interpersonal support and help from others (Due et al., 2005; Haynie et al., 2001). On the other hand, as aggression and bullying are considered more normative among boys and can often be encouraged by their peer group (Hunter, et al., 2004), this might lead them to avoid seeking help from friends.

In terms of age and coping, no significant differences emerged in the present study. Age was estimated by which year the students were in at school. The one significant difference found was that there was an increase in disclosing the bullying experience as students increased in age. The present study showed that a high percentage of 3rd year students that had been bullied would talk about it to a friend(71.8%), while only 48.2% of 1st year would do so. Although the present study does not allow for a comparison of the students' responses as the participants belong to very similar stages in their development, the following trends were, however, observed: as the age of the students increases, they are less willing to seek social support at least from a teacher (6.7%). Similarly, older students would be less likely to use internalizing responses such as crying (3.8%), and indeed have probably developed more successful responses than this, such as taking precautions (27.9%). It may be that as children grow older potentially they "learn from experience"(Smith, et al., 2001) to cope with bullying

episodes. Besides, as they approach adolescence, they will need to “stand up for themselves” (Orpinas, & Horne, 2006; Smith, & Shu, 2000).

4.4. Disclosure and Bullying

A common tactic in many anti-bullying programmes is to encourage the student who has been bullied to tell someone about this incidence and to talk about it (Skrzypiec et al., 2011). This strategy has been recommended to bullied students as an effective coping method and has been identified by experts as a preferred strategy (Slee & Murray-Harvey, 2008). There was no significant association as regards disclosure and frequency of bullying (as measured by the one or more forms of bullying experienced). Disclosure to a person has been a coping mechanism adopted by the majority of bullied students, despite the fact that 19.2 % (nearly 1 in 5 students) would not tell about their bullying experience. Friends are the persons to whom the bullied students would talk most to about the incident (64.8%), followed by parents (30.5%). Many studies (e.g., Olweus, 1993; Rigby, 1996) favour anti-bullying strategies that involved peer support: this strategy implies that other students are aware of or are informed about bullying situations at their schools and are asked to support the victim or take action against the bully.

One in five bullied students (20.0%) would disclose their bullying experience to a teacher or to their siblings. We do know that disclosing about bullying improves mental health (Cowie, et al., 2005; Smith, et al., 2004).

The advice most often given by adults, both experts and non-experts, is to “tell some-one” (Unnever, & Cornell, 2004); yet, in the present study, 48% of the students who had been bullied stated that even after having informed a teacher about the bullying incident, 31.7% never or almost never attempted to put an end to it, while 16.3% attempted to do so once in a while. Respectively, bully-victims stated a much higher percentage of teachers who had been informed about the incident and did not try to intervene (57.3%). In addition, both bullied students and bully/victims stated that there was a definite lack of collaboration between home and school in order to stop bullying behaviour (76.5% and 72.9% respectively). Fekkes, Pijpers, & Verloove-Vanhorick, (2005) found that although 53% of 9-11 year-old bullied pupils told their teachers about the incident, only one third of them found the teachers' interventions helpful. It is worrisome that in spite of there being a global trend to enhance disclosure of bullying incidents to teachers or parents, this strategy has not been accompanied by successful interventions from these adults. Further, as students move into adolescence, they are less eager to talk about their problems with adults whom they perceive as members of institutional authority, such as the school. Nevertheless, when reading these results, we need to keep in mind that bullied students and bully-victims tend to make more negative appraisals of teacher capacity to intervene successfully and resolve conflicts (Rigby, & Bagshaw, 2003).

4.5. Reactions to a Student Being Bullied and Bullying Profile

Just over half of the students stated that they would try to help a bullied student (51.9%) and another 24.5% felt that they ought to help him/her even though they would not. A very small percentage of the students claimed that they would take part in the bullying (3.3%) or believed that in some way they had been forced to participate (2.0%). Another (thankfully)

small group of students, responded that they accept bullying as a normal experience (5.7%) or thought that it was fun (3.7%). Interestingly, nearly one in ten students stated that they would just watch a bullying incident take place without feeling the need to intervene by standing up for the bullied student (9.0%).

In the present study, significantly more bully/victims would react with indifference when they saw or understood that another student their age own was being bullied, when compared to students who claimed to not be/have been involved in any bullying incidents either way. What this means is that they are more likely to accept bullying behaviour as a normal process or a few would even perceive it as "just having fun" and would stand by and watch it happen without intervening. In addition, bully/victims, when compared to students not involved in bullying, would to a much lesser extent try to help others who were being bullied, and they do not believe that they need to intervene in support of their bullied classmate. In any case, the finding in the present study that students who fall into the bully/victim category differ in their views from the separate categories of bullies and victims (in turn discussed below), as to standing up for and trying to help a fellow student who was being bullied, suggests that they comprise a distinct group who need to be addressed with great caution. When it comes to anti-bullying interventions, and in this case interventions involving peer support, (Cowie et al., 2005) need to vary depending on the children's bully status type. Other studies have shown (Andreou, 2001; Olafsen & Viemerö, 2000) that bully/victims reported using more "aggressive" strategies compared to victims and not involved children; they also tended to show significantly more anger and had a propensity for revenge (Andreou, 2011; Thornberg, Halldin, Bolmsjö, & Petersson et al., 2011).

Regarding the reactions of bullies toward bullied students of their own age, a significant number claimed that they would definitely take part in the bullying activity observed, while only a few stated that they would intervene to help the student who was being bullied by others. According to many studies (Olweus, 1993; Rigby, 1996) bullies typically have a positive attitude to violence and tend to be aggressive, impulsive and dominant in their interaction with others. On the other hand, as might be expected, the bullied students in the present study significantly more than bullies or bully/victims stated that they would definitely try to help in one way or another another student who was being bullied. Victims, generally, hold a negative attitude toward violence and tend not to be aggressive in general (Olweus, 1993).

4.6. Psychosocial Well Being, Bully Status Type and Students' Coping

In terms of bullied students' psychosocial well-being, the SDQ was used as a proxy of their psychological adjustment. There is evidence to show that bullying is associated with bullied students' mental health overtime. Alikasifoglou, et al., (2007), for example, found that bullied victims still suffer from emotional problems (e.g., anxiety and depression) 2 years after the onset of bullying which finding is confirmed by other studies (Currie, et al., 2004; Junoven, & Graham, 2001).

The present study showed overall that bully/victims scored higher than any other group (bullies, victims, not involved) on all the scales of the SDQ. This category, being involved in the bullying behaviour at times as bullies and at others as victims, as is perhaps expected, tends to be faced with significantly more difficulties in the area of positive social behaviour and peer relations, as well as suffering from hyperactivity/inattention, emotional difficulties, and

conduct behaviour problems in comparison to students who are not/have not been involved in bullying. This group (bully/victims) also scored significantly higher on the total difficulties score in comparison to the categories "not involved" and "bullies". Overall, bully/victims have the highest level of adjustment problems among all types of students involved in bullying. This finding is supported by research that has identified bully/victims as scoring higher than any other group on other characteristics, such as neuroticism and psychoticism and other (including externalizing) behavior problems (Alikasifoglou, et al., 2007). According to some researchers, bully/victims have been found to be both anxious and aggressive, as well as hyperactive in some cases (Olweus, 1993), and they tend to have a low level of self-esteem (Andreou, 2001). Kumpulainen et al., (1998) in Finland, found bully/victims to be the highest at risk group for a variety of behaviour problems. However, the results presented here are cross-sectional and it may also be the case that psychosocial well being contributes towards attributions of victimization and coping practices of bullying.

The bullied students scored higher on the prosocial behaviour scale and lower on the conduct problems scale in comparison to bully/victims; in addition, the victims scored higher in peer relationships in comparison to bullies and not involved students, although they got a lower total difficulties score in comparison to the bully/victims.

The bullies in the present study faced significantly less problems in the area of peer relationships in comparison to victims and the bully/victims. In terms of the total difficulties score, the bully/victims were those who presented most psychosocial problems, followed by the victims and the bullies.

The results of our study, similar to those of previous studies (Craig, & Pepler, 2003; Kumpulainen, Rasanen, & Henttonen, (1999), show that involvement in bullying has an impact on students' mental health and bully/victims seem to suffer most. However, despite the relationship between bullying and psychosocial problems, the cross-sectional nature of the study does not allow a causal relationship.

Regarding psychosocial well being and coping, the present study showed that the areas of positive social behaviour and conduct behaviour problems significantly differentiated students' coping strategies. More specifically, the students who stated that they would partake in the bullying of a classmate, had much fewer positive social skills than those who responded that they ought to try to help or did help their classmate. Similarly, the students who claimed that bullying was a normal experience and that it is a way of having fun, had many more conduct behavioural difficulties than those who would stand up for their bullied classmate. Students' psychosocial functioning did not appear to be associated with feeling fear of being victimized.

Several limitations of the study should be noted. The reliance on single informant self-reports might be inaccurate and there is a need for joint information from parents, teachers, and peers. Another limitation is the small number of students characterized as bullies ($n=26$) and those who had been bullied in three or more ways ($n=18$) which does not allow for a generalization of the findings. Next, the direction of relationships among bullying, coping and psychosocial difficulties cannot be determined due to the cross-sectional nature of the study. Longitudinal studies are needed to establish the relationship of bullying, coping and psychosocial well being.

Overall, the present study showed that disclosing one's experience of bullying is a common practice among students; this practice, though, needs to be accompanied by a supportive relational context that is able to handle bullying incidents and engage systematically in the students' well being. Second, students' reactions to a classmate being bullied are significantly

associated with bully–victim status types and students' psychosocial well being, with the group of bully/victims being severely burdened. Finally, according to the present study, differences between the coping strategies used by bullied students, bullies or bully/victims are likely to rest not on the frequency of bullying but on students' psychosocial well being. These findings point to interventions that acknowledge the different needs of students within their school setting and question simplistic programs that underestimate the complex relation of bullying, coping and well being.

ABSTRACT

Although research has identified a number of ways by which bullied students cope with the negative effects of bullying, less research has been carried out in relation to the parents' awareness of bullying and suggested ways of dealing with it. The current study undertakes this challenge by collaborating with parents as agents of information regarding (their) children's bullying experiences and coping strategies. The aims of the present study are 1) to estimate the frequency of bullying according to parental views 2) to investigate the parents' views regarding the coping strategies their bullied children usually adopt 3) to investigate the parental coping in relation to bullying and to 4) to search for the association between coping strategies as perceived by parents and parenting style. 1127 parents whose children were attending 14 primary schools in Northern Greece completed a 12-pages Questionnaire. Overall, our findings contradict the main literature that talks about high parental underestimation of bullying, as only a small percentage of parents-mainly those who had boys-reported not being aware of their children's coping strategies when bullied. Disclosure was not only indicated as the bullied children's favorite coping, but the most recommended one by parents. In terms of parenting styles, authoritative practices were the first choice of parents, followed by authoritarian and permissive practices. The relationship between parenting and coping strategies are discussed within the light of anti-bullying interventions that are also addressed to parents.

Keywords: Parents' views on bullying, parents' and children's coping strategies, parenting practices.

INTRODUCTION

Bullying has a negative impact on both the lives of children and adolescents significantly contributing to their psychological state (Bukowski & Sippola, 2001; Olweus, 1993; Rigby, 2001, 2002). Researchers have reported psychosocial difficulties for bullied students, bullies and bully-victims that appear to restrict them in the areas of their social, psychological and academic functioning overtime (Alikasifoglu, Erginoz, Ercan, Uysal, & Albayarak-Kaymak, 2007; Crothers, Kolbert, & Barker, 2006; Fitzpatrick & Bussey, 2011; Thornberg, 2011; Thornberg, Halldin, Bolmsjö, & Petersson, 2011).

Although the incidence of bullying is overall worrisome, parents are mainly uninformed of their children's bullying experiences (Bauman & DelRio, 2005; Crothers et al., 2006; Naylor, Cowie, Cossin, De Bettencourt, & Lemme, 2006). Nearly half of the bullied students do not tell their family about the bullying situation they are going through (Sawyer, Mishna, Pepler, & Wiener, 2011). Even when the parents are told, they do not seem to know the best ways to help their child overcome the situation (Deliyianni-Kouimtzis, 2005; Houndoumadi & Pateraki, 2001; Sawyer et al., 2011; Tsiantis et al., 2007). Moreover, according to some studies, the methods parents suggest to cope with bullying seem both unrealistic and ineffective (Kochenderfer-Ladd, 2004; Sawyer et al., 2011).

Despite the fact that families play a significant role in the prevention and the intervention of bullying, the majority of researchers have focused on the views and perceptions of students and teachers, which arguably confines bullying to the school context (e.g., Bibou-Nakou, Tsiantis, Assimopoulos, & Chatzilambou, 2012; Boulton, Karellou, Laniti, Manousou, & Lemoni, 2001; Deliyianni-Kouimtzis, 2005; Holt & Keyes, 2008).

Parenting is significantly associated with aggression and bullying in children and adolescents (Ahmed & Braithwaite, 2004, 2004a; Duong, Schwartz, Chang, Brynn, & Shelley, 2009; Georgiou, 2008a, 2008b; Olweus, 1994; Orpinas & Horne, 2006; Pontzer, 2010). Specifically, there is evidence to suggest that poor parenting, measured in terms of parenting styles such as a permissive or authoritarian style, has been significantly correlated with aggression in general and bullying in particular (Baldry & Farrington, 2005; Bibou-Nakou et al., 2012; Rigby, 1996). Although many studies have stressed out the link between family environment and bullying, the focus has mainly been on the family factors that lead to bullying such as marital discords, parental styles, family conflicts etc (Bowers, Smith, & Binney, 1994; Olweus, 1993). Only recently, researchers have attempted to investigate the relation of family upbringing and children's coping strategies (see Espelage & Swearer, 2003; Smith, 2004).

To our knowledge the international literature lacks studies that investigate the parents' views regarding bullying and the suggested parental coping strategies for dealing with it. The present study aims to contribute towards this line of argumentation.

Resilience, that is, the process of overcoming stressful events is mainly based on successful coping strategies. These adequate strategies are enhanced, among other factors, by good-enough parenting. By researching parents' views regarding bullying, the present study hopes to contribute to a wider understanding of the phenomenon; moreover, parental perspectives can enrich anti-bullying prevention and intervention efforts and lead to significant protective factors for the reduction of bullying (Eslea & Smith, 2000). Including parents as informants might also lead to the deconstruction of family misunderstandings and negative stereotypes

(Andreou, 2011) and could help parents act as models for effective coping strategies (Craig, Pepler & Blais, 2007).

REVIEW OF COPING THEORIES

Although coping as the way we attempt or manage to solve our daily problems is extremely important for the well being of us all, there are many classifications and typologies that produce difficulties for a simple or straightforward way of dealing with stressful situations. The conceptualization and measurement of coping strategies in general form a complex area that is even less researched in children and adolescents. Several theories have been developed that attempt to classify coping behaviors, mainly in terms of their outcome (positive or negative) or their functions (Lazarus & Folkman, 1984). Though quite general, problem-focused and emotion-focused coping has been the most widespread form of classification. Avoidance versus approach coping is another means of typology that equates approach with problem-focused coping, while avoidance equates with emotion-focused strategies. The importance of positive coping lies mainly in the fact that there is a strong correlation between coping strategies and psychological well-being.

From the literature review regarding coping strategies and bullying, the majority of the studies focused on the coping of bullied students and they associate problem-focused and approach coping strategies with the cessation of bullying, developing successful peer relationships and better psychosocial development (Kochenderfer-Ladd & Skinner, 2002). In addition, coping has been researched in relation to the appraisal of the situation by the victimized students: for example, it has been found (Hunter & Boyle, 2004) that victims' positive appraisal is associated with help or support-seeking and lowered stress (Hunter, Mora-Merchàn, & Ortega, 2004).

Coping has also been discussed in terms of coping efficacy (Bandura, 1997; Benight & Bandura, 2004), which is one's ability to deal successfully with stressful or negative events by appraising these as keeping them under control. Bandura (1997) showed that coping self-efficacy results in adequate coping behavior and lessens the possibility of subsequent or chronic stressors. Many researchers have focused on effective ways of coping with peer aggression and bullying where they found that coping self-efficacy is associated with a lower risk of psychological maladjustment of the bullied student (Hall, 2006; Kochenderfer-Ladd, 2004; Kochenderfer-Ladd & Skinner, 2002; Mahady Wilton, Craig, & Pepler, 2000; Morrison, 2003; Sandstrom, 2004). Singh and Bussey (2009)'s study is quite interesting as by using six areas as measure of coping self-efficacy on bullying, they attempt to thoroughly investigate the concept of coping self-efficacy. These areas focused on both behavioral (such as help seeking and problem solving) as well as cognitive coping strategies (such as beliefs of self-blame or loss of control).

According to Connors-Burrow, Johnson, Whiteside-Mansell, McKelvey, & Gargus (2009), in theory, there are two ways to discuss the relationship between coping such as searching for social support and children's functioning. The first way refers to the main effect model and coping is regarded as a protective factor for all children irrespective of whether or not they are involved in bullying or not. The second way is based on the stress buffer model and

acknowledges coping strategies as protecting mainly children at risk, and in our case, bullied children.

Another way of discussing coping with bullying can be to adopt Rigby's et al.(2010) distinction between two general ways of anti-bullying policy: the first of these is known as a rules-sanctions strategy, and sets clear rules against bullying followed by consequences for those who break them; the second one is a problem solving approach that deals with bullying in a non punitive way and is based on a care moral orientation to understand relationships (Ellis & Shute, 2007).

BULLIED STUDENTS' COPING STRATEGIES

The chronic nature of bullying along with its negative psychosocial consequences is associated with the ineffective or unsuccessful coping strategies of the bullied students (Hunter & Borg, 2006). Lately, there has been research on bullying that focuses on the coping strategies used mainly by the bullied student (Salmivalli, Karhunen, & Lagerspetz, 1996; Smith, Shu & Madsen, 2001). Overall, the studies on coping with bullying suggest that it varies by gender, age, bully-victim status type and type of bullying (direct versus indirect).

For example, Olafsen & Viemerö (2000) and Andreou (2001) found that bully/victims reported using more "aggressive" strategies compared with victims and children who were not involved. Moreover, there are studies that have looked at coping strategies in relation to different types of victimization such as social isolation, rumors, name calling etc. Bijttebier & Vertommen (1998), Kristensen & Smith (2003) and Olafsen & Viemerö (2000) found that children tend to seek social support and ask help in overt bullying situations such as stealing, breaking belongings etc. The researchers suggest that this kind of bullying is both easier to observe and prove. In addition, some studies have found significant associations between frequency of bullying and coping strategies (Andreou, 2001; Bijttebier & Vertommen, 1998; Hunter & Boyle, 2004) and children's appraisals and attributions regarding bullying (Lazarus, 1999). More specifically, intent and power imbalance have been found to have a strong relation to coping since there is evidence to suggest that the children who believe that they are seriously threatened and feel helpless at the same time, prefer emotion-focused strategies (Bowker, Bukowski, Hymel, & Sippola, 2000; Hoffner, 1993). Hunter, Boyle, & Warden (2004) also found that the bullied children's negative appraisals such as low control have been associated with emotion-focused strategies like wishful thinking.

Overall, victims' support-seeking leads to better ways of coping with bullying and enhancement of children's well being (Giannotta, Settanni, Kliever, & Ciairano, 2009; Matsunaga, 2011; Smith, Talamelli, Cowie, Naylor, & Chauhan, 2004). Among the successful ways of coping, help seeking has been acknowledged as one of the most effective ways in terms of students' better psychological adjustment (Hunter & Borg, 2006) in comparison to coping with bullying on their own, without disclosing one's bullying experience (Smith, 2000, 2004). On the other hand, receiving inadequate support could exacerbate the mental health of bullied adolescents, according to Rigby (2000). That is why emotional support provided by those whom the children trust (families, teachers, friends) has been found to be a significant factor in encouraging children to disclose their bullying experience (Matsunaga, 2010). Reducing stress

and bringing bullying to an end might be achieved by the family's support toward children who have experienced bullying practices.

Problem-focused coping includes strategies of help and support seeking, and active ways of problem solving; on the other hand, emotion-focused strategies are mainly ways that liaise with the negative emotions of the bullied children such as anger, crying, self-blame and self-pity, avoidance strategies, or pretending that nothing really happened (Hunter & Boyle, 2004; Skrzypiec, Slee, Murray-Harvey, & Pereira, 2011; Tenenbaum, Varjas, Meyers, & Parris, 2011).

According to the literature, 43-73% of bullied students tend to ignore the fact, 70% cope by ignoring the person who bullies them, while 26-32% express anger, self-pity, a sense of helplessness and a tendency for revenge (Houndoumadi & Pateraki, 2001; Sharp, 1995, in Hunter & Boyle, 2004). Girls have been found to pity themselves significantly more in comparison to boys, whereas older students and bully-victims show significantly more anger and a tendency for revenge (Andreou, 2011; Thornberg et al., 2011). Coping has been found to also depend on the frequency of bullying (Athanasziades & Deliyanni-Kouimtzis, 2010; Houndoumadi & Pateraki, 2001; Naylor, Cowie, & Del Rey, 2001; Skrzypiec et al., 2011).

As already mentioned, the assessment of effective and successful coping is a complex issue, since it is defined by both individual and environmental factors and poses the question of who is to define what is effective for whom. Some of the researchers for instance claim that the distinction of strategies as passive and active/assertive is rather crude or too simplistic and have found that ignoring the bullying experience, or avoidance of the bully might be classified as active ways of dealing with the problem, provided that these ways result in an end to bullying (Cowie, 2004; Kochenderfer-Ladd & Skinner, 2002; Rigby, 2002). On the other hand, there are studies that show that the above mentioned strategies are definitely passive and do not work effectively to deal with the bullying experience (e.g., Mahady-Wilton et al., 2000). Besides, there are researchers that argue for the enhancement of peer relations as one of the most effective ways of coping with bullying and securing children's psychological well being (Bukowski & Sippola, 2001; Card & Hodges, 2008; Cowie, 2004; Nishina, 2004; Pellegrini & Bartini, 2000; Salmivalli & Voeten, 2004).

The majority of the studies argue that disclosing the bullying experience is the first step to putting an end to it (Cowie, 2004; Deliyanni-Kouimtzis, 2005; Mahady-Wilton et al., 2000; Rigby, 2002), as a lack of disclosure does not help in recognizing the problem (Matsunaga, 2009; O'Moore & Minton, 2004). Generally speaking, self-disclosure has been acknowledged as a support network (Matsunaga, 2010) that helps victims to escape from bullying and to improve their mental health (Hunter & Borg, 2006; Smith et al., 2004), though it seems that with age, the disclosure of the bullying situation fades (Naylor et al., 2001). However, despite the importance of disclosure, it is likely that many victims are unwilling to disclose their experience: they are afraid of the bullies retaliating (Sawyer et al., 2011; Skrzypiec et al., 2011; Unnever & Cornell, 2004); they fear that their experience will become known by undesired people and will eventually result in their feeling ashamed about their peer relations; and lastly, they believe that those they choose to disclose their experience of having been bullied often misunderstand the situation and thus cannot provide adequate coping support (Mishna & Alaggia, 2005; Smith, 2000). For example, there is evidence to suggest that advice given by the parents as a form of coping can be appreciated by the children as intrusive, critical, and/or face threatening (Feng, 2009; Goldsmith, 2004). Since bullying is stigmatizing and bullied children are afraid that others might criticize or blame them, they generally prefer not to share

this information (Rigby & Barnes, 2002; Smith, 2000). Besides, bullied children are often viewed as possessing some undesirable characteristics such as the inability to stand up for themselves or lack of social skills and low levels of popularity among peers (Stockdale, Hangaduambo, Duys, Larson, & Sarvela, 2002).

In addition, disclosing one's experience of bullying is dependent on the given relational context (see, e.g., Greene, 2009) and the parents' disposition, practices and relational ways. Parents unable to handle the bullying experience, showing no interest at all, or reacting in a negative way, affect children's disclosure decision making (Mishna, 2004).

Rigby (2002) has also pointed out that students do not disclose their bullying experiences, since they believe that it is something that also happens to adults and they have to put up with it. Skrzypiec et al. (2011) arguably note that disclosing one's experience and help seeking is a typical way of dealing with bullying among girls, whereas this does not seem to work quite effectively for the male students.

Students' coping is significantly associated with parenting practices as well. In their study of adolescent students, Unnever & Cornell (2004) found that those who, among other factors, described their parents as using coercive discipline were less likely to report being bullied. Further, Conners-Burrow et al. (2009) found that support from parents acted as a buffer against depression for all children, irrespective of their bully status. Moreover, in the cases of high parental support, teacher support did not have a significant impact on children's well being when having been bullied. By providing parental care and emotional support the family can help in providing better coping strategies and act as an enhancement of children's resilience. In addition, children are able to terminate their victimization earlier than those whose family has not been informed of the bullying (Bowers et al., 1994; Hunter & Borg, 2006; Hunter et al., 2004). Naylor et al.'s (2001) study has demonstrated that seeking social support from families and peers helped victims cope with bullying and maintain resiliency. In other words, children's trust in their parents leads to disclosing bullying experiences and better ways of coping (Matsunaga, 2009; Smetana, Metzger, Gettman, & Campione-Barr, 2006).

PARENTAL VIEWS AND STRATEGIES REGARDING BULLYING

As already stated, many parents tend not to be fully aware of the nature of bullying (Bauman & Del Rio, 2005; Crothers et al., 2006; Naylor et al., 2006). Specifically, Horne, Orpinas, Newman-Carlson and Bartolomucci (2008) argue that most adults share a number of misleading views regarding bullying; these views potentially block their awareness of the severity of the problem and their active engagement in dealing with it. Some of the misleading views are the following: many adults believe that bullying forms part of a normal developmental process among peer groups (Eslea & Smith 2000; Sawyer et al., 2011), that fades away naturally overtime; others believe that some children are born to be violent, and there is no use in intervening in the process of upbringing. Another myth about bullying refers to gender differences, allowing males to exert violence. Moreover, some adults consider only the overt aggressive acts, both physical and verbal, as bullying thus underestimating covert aggressive behaviors such as social exclusion or rumors spreading (Holt & Keyes, 2008; Naylor et al., 2006; Smith & Sharp, 2003). While another group of adults think that bullied students deserve what they get, having provoked with their practices. As Eslea and Smith, (2000) point

out, these kinds of perceptions have been proved to be strongly ineffective for seriously dealing with bullying.

Specifically, in the study by Eslea and Smith (2000), it was shown that the majority of parents whose children were between 6-11 years old view bullying negatively and show positive feelings of concern and support towards the bullied students; on the other hand, however, it seems that the parents did not fully understand bullies' behaviour. In a national Greek study, Deliyianni-Kouimtzis, Gonida, Kioseoglou, and Zafeiropoulos (2008) found that over 40% of parents were concerned about their children experiencing bullying with whom they seemed to empathize. On the other hand, the findings of the same study showed that the parents of bullies held a much less positive attitude towards the bullied students, in a way blaming them for their involvement as victims. Eslea and Smith (2000) found that although most parents seem to be sympathetic towards bullied students, there was little association between parental attitudes and those of their children. Harper (2011) showed that both children and parents attribute bullying to individual factors related to the bullies themselves, such as innate characteristics.

WHY PARENTAL VIEWS ARE IMPORTANT?

Many anti-bullying interventions that are often advocated by researchers are aimed at improving both the victims' and bullies' coping strategies (Cowie & Sharp, 1994; Olweus, 1993; Smith et al., 2001). Our study attempts to explore the role of the parents' views regarding bullying and possible ways for providing support to their children who have been victims of such behaviour.

There are several reasons why an examination of the parents' suggestions on how to stop bullying can provide rewarding insight into anti-bullying interventions research. To begin with, even though the important role of the family in helping the victim's coping process has been well documented (Naylor, et al., 2001), the fact that generally the family lacks necessary information on the child's bullying experience is of great concern. There are several reasons as to why this discrepancy between the children's bullying situations and their parents' knowledge of it exists: the children may not disclose their experiences due to reasons mentioned earlier in the previous section. This gap in the parent- child relationship poses a considerable risk factor: bullying places severe stress on the victim and the family could act as a buffer and become the protective factor in the child's coping (Matsunaga, 2009). Although the family can provide a valuable coping resource for victims of bullying (Naylor et al., 2001), it appears that many families are never given the opportunity to offer their support, since they remain uninformed of their children's bullying experiences. Fekkes et al. (2005) found that about half of the parents of bullied children were unaware of their children's being bullied, a finding that confirms earlier studies (Rigby & Barnes, 2002; Smith, 2000).

Second, according to Matsunaga (2009), the children's lack of well being might be exacerbated if they do not get support from their families, along with the already mentioned negative influence of bullying on victims' well-being. The same researcher (Matsunaga, 2009) in an attempt to identify what distinguishes informed families who provide care and support from those that are uninformed, showed that family communication could act as a significant protective factor in relation to their children's disclosure of bullying. More precisely, Open-

Affectionate families, whose members opt for information sharing e.g., high openness, emotional/ instrumental support, regular routine interaction, and low avoidance are more instrumental in bestowing the needed care and support than detached families, whose members have relatively low openness and high avoidance orientations. Further, Baldry, & Farrington, (2005) showed that highly supportive parenting is related to lower levels of victimization. Crothers et al. (2006) from their study on middle school students' preferences for anti-bullying interventions showed that the participants proposed parental involvement of both bullied and bullies as one of the most effective ways to stop the phenomenon. These findings were confirmed by Frisé & Holmqvist, (2009) in their study of the same age group of adolescents. Parental involvement was the third common category to be included by 13-year old students; however this was not the case for 16-year olds. From their study, Connors et al. (2009) found that parental support acted as a buffer against depression for all children, irrespective of their bully status. Moreover, where there was high parental support, it appears that teacher support did not have a significant impact on children's well being. Asking the parents themselves about ways to stop bullying is likewise of great importance, because it directly involves them in the selection and evaluation of psychological interventions that their children adopt.

Third, there is strong evidence to suggest that many victims prefer to talk about their bullying experiences with a family member in their own home than discuss it with a teacher (Eslea & Smith, 2000). Further, teacher consultation with parents has been found a successful way to reduce bullying at schools (Smith & Sharp, 1994).

COPING STRATEGIES SUGGESTED BY PARENTS

As mentioned earlier, there have been many recent studies that have examined students' perceptions of how victims should cope with bullying situations (Kanetsuna, Smith, & Morita, 2006; Kristensen & Smith, 2003; Smith, Mahdavi, Carvalho, Fisher, Russell, & Tippet, 2008; Smith et al., 2004); however, parents' perceptions of the effectiveness of different bullying interventions (with victims' coping strategies being just one of them) have not been widely examined (Harper, 2011). According to Sawyer et al. (2011), most parents stress out the significance of informing the teachers, a suggestion confirmed by other studies as well (Giannakopoulou et al., 2010; Harper, 2011). Other coping suggestions include retaliation, ignoring the bully, and enhancement of positive social behaviour acting as a buffer for the stressful impact of bullying (Harper, 2011; Sawyer et al., 2011). According to the data by Eslea & Smith (2000), 61% of the parents supports the view that "one has to defend oneself", whereas 50% of them argue that "children should act on their own and not ask for others' support". In her study, Harper (2011) has shown that parents mostly prefer strategies favoring social support in comparison to strategies of retaliation or isolation.

Mahady-Wilton et al. (2000) found that parental suggestions oriented to ignoring bullying are significantly associated with chronic bullying and more internalizing problems (Kochenderfer-Ladd, 2004). It is as if they do not seem to realize the stress caused by bullying and the situation their children are involved in. In addition, according to Rigby (2002), there are parents who would prefer their children to be in the bully rather than the victim status.

Given that effective coping strategies such as problem solving and help-seeking are related to reduced bullying (Craig et al., 2007; Kochenderfer-Ladd & Pelletier, 2008), parents need to

realize that many of their suggestions are not realistic, do not take into consideration the power imbalance among peer group relationships and could lead to their children being even more at risk (Craig et al., 2007; Harper, 2011; Sawyer et al., 2011).

It is worth noting that parents' response when asked to participate in studies about bullying is most often positive, a fact that indicates the family's recognition of the problem (Rigby (2002). A study analyzing telephone calls through a parentline (Donnellan, 2006), demonstrates the willingness of families to collaborate with their children's schools, as well as illustrating their disappointment from their experiences so far. Parents according to Donnellan (2006) and Rigby (2002) would like to be informed and included in anti-bullying programs.

From a national Greek study (Deliyianni-Kouimtzis et al., 2008) the participating parents stress the need for a positive school-home collaboration (46.9%), for the planning of intervention programs (19.9%), for specific help from experts (19.4%), for maintaining punishment (17.9%) and for the involvement of teachers in bullying events (16.3%).

The development of positive social skills and the emotional support along with children's involvement in extra-curriculum group activities have been also suggested as effective coping strategies by a group of parents in the study of Sawyer et al. (2011).

Bully-victims or bullies also need to be helped: not being rejected by parents, firm boundaries and emotional support contribute to successful results (Lam & Liu, 2007).

PARENTING PRACTICES

According to Baumrind (1991), there are 3 main styles that differentiate the way parents bring up their children: the permissive, the authoritarian and the authoritative. These styles differ in the way parental control is exerted along with other factors, such as family communication, emotional support and decision making. Authoritative parents for example, favor, among other things, negotiation and a clear two-way communication and mutual understanding (Estevez, Musitu, & Herrero, 2005).

The authoritative model has been negatively associated with bullying (Baldry & Farrington, 2005; Georgiou, 2008a) measured in terms of family communication (Estevez et al., 2005; Spriggs, Iannotti, Nansel, & Haynie, 2007; Stevens, De Bourdeaudhuij, & Van Oost, 2002), parental involvement (Barry, Dunlap, Lochman, & Wells, 2009; Georgiou, 2008a; Mizell, 2003), warmth and positive emotions (Giovazolias, Kourkoutas & Mitsopoulou, 2009; Idsoe, Solli, Cosmovici, 2008; Lam & Liu, 2007; Ybarra & Kimberly, 2004) setting limits (Barry et al., 2009; Idsoe et al., 2008; Ybarra & Kimberly, 2004), autonomy (Curtner-Smith et al., 2006; Idsoe et al., 2008) and parental support (Ang, 2008; Baldry & Farrington, 2005; Dimakos, 2005).

The authoritarian model, on the other hand, has been positively associated with bullying (Curtner-Smith et al., 2006; Georgiou, 2008a). The following factors have been researched, among other variables: overprotection and parental anxiety (Ang, 2008; Barry et al., 2009; Georgiou, 2008a, 2008b) severe discipline (Barry et al., 2009; Curtner-Smith et al., 2006; Duong et al., 2009; Stevens et al., 2002; Ybarra & Kimberly, 2004), abuse-neglect (Shields & Cicchetti, 2001), and parents' stigmatizing their children (Pontzer, 2010). Parental involvement and excessive parental control have been related to children's victimization (Stevens et al., 2002).

The above reported studies focus on the significance of parenting styles on bullying, although in no way should they be regarded as single causal factors for the occurrence of the behaviour (Stevens et al., 2002; Mitsuru, 2010). Respective attributions tend to blame the parents and absolve other contextual factors for the appearance of bullying. Parental blaming appears to be well maintained by some school staff, which only hinders school-parent collaboration in eliminating or reducing the phenomenon.

THE PRESENT STUDY

Little research has been done in the area of parents' perceptions of bullying, although there is evidence to suggest that family factors such as parental discipline, family communication, parenting styles, are significantly correlated with aggression in general and bullying in particular (Bibou et al., 2012; Bowers et al., 1994; Olweus, 1978).

The way parents perceive and define bullying is strongly associated with their ways of acting or intervening in order to put an end on it (Sawyer et al., 2011). When informed about their children's victimization, the majority of parents feel anger, disappointment and worry about what their children are going through; They are particularly concerned about the negative consequences of bullying on their children's academic functioning.

The ways parents intervene to prevent or deal with bullying in association with their parenting practices are acknowledged as significant factors for the children's decision to disclose their bullying experiences (Matsunaga, 2009; Sawyer et al., 2011).

It has been documented that parents' views regarding their children's bullying or bullying in general are essential components in planning and implementing anti-bullying programs (Eslea & Smith, 2000; Farrington & Trofi, 2009; Olweus, 1993; McNeely, Whitlock, & Libbey, 2010). Besides it is parents who should be informed first about their children's bullying, since ideally, they know them better than anyone else (Braaten, 2004) and can support them in numerous ways (O'Moore & Minton, 2004).

The present study sought to investigate parents' views regarding their children's bullying experience, how the children deal with bullying in order to cope, parents' coping and their suggestions to children to cope in hypothetical cases of their child being either a bullied or a bully student. This is in light of the fact that parental coping strategies have not been researched/examined thoroughly and in view of the literature that shows that most parents rate the frequency of bullying to be much lesser than what their children do actually experience (Fekkes et al., 2005; Stockdale et al., 2002).

More specifically, the aims of the present study are 1) to estimate the frequency of bullying according to parental views 2) to investigate the parents' views regarding the coping strategies their bullied children usually adopt 3) to investigate the parental coping proposed to a child when being bullied 4) to search for the parents' coping strategies in the hypothetical case of living with a bullied child or a bully and to 4) to search for the association between coping strategies as perceived by parents and parenting style.

METHOD

Participants

There were 1127 parents whose children were attending 14 primary schools in Northern Greece who participated in the study. The majority of the participants were women (81.2%), aged from 31-40 years (54.5 %), who were native (85.4%) and living in Thessaloniki (68.8%). Most were married (89.9%), with two children (51.9%) and had secondary (36.3%) or tertiary school education (25.8%).

Procedures

The questionnaires used were constructed on the basis of a) 3 pilot focus groups with parents with whom the first researcher discussed their views regarding bullying and their suggested ways of coping with it, b) the Olweus Questionnaire, (1996), "Bullying and Victimization Questionnaire", nationally adapted by Deliyianni-Kouimtzis, Athanassiadou, Konstandinou, Papathanassiou, & Psalti (2005) and c) the «Teachers' Knowledge and Attitudes about School Bullying Questionnaire» by Nicolaides, Toda, & Smith (2002). The final questionnaire on the children's involvement in bullying and coping strategies was translated into Albanian and Russian by two native speakers living in Greece, and translated back into Greek by two other people. The questionnaire was administered to individual classes by the first author, in order for each student to take it home to their parents, with the class teacher present. The researcher explained that the questionnaire was about bullying in school and about finding out the ways parents could help in different bullying situations. A definition of bullying and examples of how to fill in the questionnaire were included in order to ensure that the parents understood what was required. It was expressly stated (both orally to teachers and students, as well as in written form) that parents should not put their names on the questionnaire and that their responses would be read by none other than the research team. It was also stressed that for some whatever reason if any of the parents did not wish to partake in the study were in no way obliged to do so, or if they did take part but came across one or more questions that they preferred not to answer, they could leave these blank and go on with the next question. The first researcher distributed 1670 questionnaires to parents whose children attended 8 public primary schools in Thessaloniki and 6 in other rural areas, in the province of Macedonia. The schools were chosen on the basis of the willingness of the school staff to collaborate with the researchers who then applied the snowball method. This phase of the research started in November 2009 and ended in April 2010. 1127 parents (67.5%) completed the 12-pages questionnaire that was returned to the first researcher.

Statistical Analysis

The statistical package SPSS v. 18 (SPSS Inc., Chicago) was used. Principal Component Analysis with Varimax rotation was used to group various questionnaire statements into meaningful scales; the number of factors was selected using Kaiser's criterion (eigenvalue > 1). The reliability of the scales produced was measured by Cronbach's α . Parents' answers to the questionnaires were ordinal or dichotomous variables and were analysed with non-parametric

methods, such as Pearson's X^2 , Mann-Whitney's U test and Spearman's correlation coefficient ρ . Scales created by the summation of answers were treated as quantitative variables and were analyzed with parametric methods, such as Student's t test. The significance level was set to 0.05

Measurements

The study contained a number of psychological, behavioral, and relational measures, as this was part of a larger research project; however only those parts of the research that are relevant to the current chapter are reported in the following sections. Specifically, we present the 5 scales:

1) Questionnaire on the Experience of Bullying According to Parents' Views

As background information, participants' experience of their children's bullying was assessed. In the study questionnaire, the researchers adapted Olweus' (1993) definitions of bullying and assessed several different forms of bullying. With slight revisions, these have been incorporated into an adapted version of the Olweus Bully/Victim Questionnaire, used in a national study (Deliyianni-Kouimtzis et al., 2005). The questionnaire divides experiences of bullying into: *physical bullying*, being hit, kicked, pushed, shoved around; *attack on property*, having had money or other things taken away from one, or damaged; *verbal bullying*, being called mean and hurtful names or being threatened (further distinguishing between *racist* and *non-racist* forms of verbal bullying); *indirect bullying*, having other children tell lies, spread rumors, to try to make others dislike one; and *social exclusion*, students purposely not including some children in activities, excluding one from their group of friends, or completely ignoring one. The 14 items of the questionnaire were in regards to, on the one hand the children as victims and on the other the children as bullies. A 4 Likert-scale (never-seldom-often-very often) was used to complete the questionnaire.

2) Questionnaire on the Coping Strategies of the Bullied Children According to Parents' Views

A Self-Report Coping Measure was used to investigate the coping strategies of the bullied children, according to their parents' views. The questionnaire included 13 statements-coping strategies that would cover a wide range of coping practices such as: informing the teacher, or the family, help seeking from friends, not telling anything, crying, avoidance, ignoring the bullying, retaliation, refusal to go to school. Parents had to indicate, on a dichotomous scale (0="no", 1="yes") their views about whether or not their bullied children use each of the coping responses to deal with bullying. A Principal Components Analysis (Varimax rotation) confirmed a three factor structure of the scale. These three factors explained 39, 22% of the total variance (14.35%, 12.65 % and 12.22 % for each of the three factors respectively). The first factor consisted of 4 items and measures *approach or problem-focused coping* strategies. The second factor consisted of 3 items and measures *avoidance* while the third factor consisted of 4 items and measures *disclosure*. Two of the items were excluded from the scale because they had low loadings on the factors. Items on each scale were added together and their values were standardized as a score from 0 to 1, where 0 indicates no adoption and 1 indicates full adoption of the strategy (see Table 1).

Table 1. Factor Analysis of coping of bullied children, according to parents

	Factors		
	I	II	III
Approach/ problem-focused coping ($\alpha = .48$, $M = .14$, $SD = .20$)			
Takes precautions.	.71		
Help seeking from friends.	.64		
Asks from the bully to stop it.	.52		
Avoids the bullying situation.	.44		
Asks for revenge.	.39		
Avoidance/passive ($\alpha = .43$, $M = .12$, $SD = .21$)			
Refuses to attend school.		.75	
Bursts into tears.		.74	
Runs away/ is hiding.		.44	
Disclosure ($\alpha = .36$, $M = .66$, $SD = .22$)			
Tells about it to me/or the other spouse.			.71
Won't say anything.			-.66
Tells about it to a school staff.			.53
Tells about it to sibs.			.42
Eigen value	1.72	1.51	1.47
% of the total variance	14.35	12.65	12.22

3) Questionnaire on Parental Coping Strategies Recommended for a Bullied Child

A Self-Report Coping Measure was used to investigate the coping strategies the parents would recommend to a child being bullied, based on the following question: "What would you as a parent recommend to a child who was being bullied?". The questionnaire included 9 statements-coping strategies that would cover a wide range of coping practices such as: retaliation, revenge, ignoring, avoidance, help seeking from friends or adults. Parents had to indicate, on a 4-point scale (from "strongly agree" to "strongly disagree") the ways of coping that they would recommend to a child being bullied. In this questionnaire, the emphasis was given to what a parent would recommend to a child in order to manage the bullying experience and includes strategies mainly based on the literature of children's coping. A Principal Components Analysis (Varimax rotation) confirmed a three factor structure of the scale. These three factors explained 56.85 % of the total variance (20.60 %, 18.99 % and 17.26 % for each of the three factors respectively). The first factor consisted of 3 items and measures *disclosure*. The second factor consisted also of 3 items and measures *retaliation*, whereas the third factor consisted of 2 items and measures *avoidance*. One item was excluded from the scale because it had low loadings on the factors. Items on each scale were added together and their values were standardized as a score from 0 to 1, where 0 indicates no adoption and 1 indicates full adoption of the strategy (see Table 2).

Table 2. Factor analysis of recommended coping strategies for a bullied child

	Factors		
	I	II	III
Disclosure ($\alpha = .41$, $M = .93$, $SD = .11$)			
To tell about it to a teacher.	.80		
To tell about it to his/her parents.	.75		
To ask from the bullies to stop it.	.57		
Retaliation ($\alpha = .42$, $M = .36$, $SD = .21$)			
Counter-aggression.		.80	
To do what bullies are doing to him/her.		.76	
To seek help from friends.		.43	
Avoidance ($\alpha = .49$, $M = .58$, $SD = .29$)			
To walk away.			.81
To ignore bullying.			.79
Eigen value	1.65	1.52	1.38
% of the total variance	20.60	18.99	17.26

4) Questionnaire on the Parental Coping Strategies for Bullied Children and Bullies

A Self-Report Coping Measure was used to investigate the parental coping strategies the participants would hypothetically use in the case of their child being involved in bullying as a victim (the leading question was: “As a parent what would you do in the case of your child being bullied?”) or as a bully (the leading question was: “As a parent what would you do in the case of your child being a bully”). The questionnaire included 14 statements, seven of which were about the status of the child as a victim and the other seven about the status of the child as a bully. In this questionnaire, emphasis was given to the type of coping a parent would choose in order to help their child overcome bullying. The two subscales (child as victim and child as bully) were identical except for the two following items: The items of the first subscale (hypothetical victimized child) “I would listen carefully to what he/she said, and I would try to support her/him” and “I would blame him/her for provoking such a behavior” were replaced by the items “I would talk with her/him and I would try to explain to him what is wrong with bullying other children, without any blaming” and “I would punish her/him” in the second subscale (hypothetical bully). Parents had to indicate, their coping ways on a 2-point scale (0 = “no”, 1 = “yes”).

A Principal Components Analysis (Varimax rotation) confirmed a two factor structure of the first subscale (see Table 3). The first factor consisted of 3 items and measures *inwards-oriented* coping (e.g., I would listen to her/him carefully and I would try to support her/him), whereas the second factor consisted of 2 items and measures *outwards-oriented* coping (e.g., I would talk about it with the bully’s parents). That is, parents would make a distinction between inwards oriented or private practices addressed to the family and close friends and outwards oriented or public practices addressed to others, the bully’s parents or the school. Two items of the scale were excluded because they had low loadings on the factors. Items on each scale were added together and their values were standardized as a score from 0 to 1, where 0 indicates no adoption and 1 indicates full adoption of the strategy (see Table 3). In this subscale, parents would focus on outward strategies rather than on private, inwards-oriented coping.

Table 3. Factor analysis of parental coping strategies (hypothetical case of the child as a victim)

	Factors	
	I	II
Inwards-oriented coping ($\alpha = .35$, $M = .53$, $SD = .29$)		
I would listen to him/her carefully and I would try to support him/her.	.69	
I would try to solve any family problems that might have an impact on my child's behavior.	.68	
I would talk with his/her friends without blaming them.	.58	
Outwards-oriented coping ($\alpha = .16$, $M = .79$, $SD = .28$)		
I would talk and I would inform the bully's parents.		.81
I would inform the school and I would talk with them about it.		.57
Eigen value	1.23	1.12
% of the total variance	25.77	22.44

A Principal Components Analysis (Varimax rotation) confirmed a three factor structure of the second subscale (parental coping in the hypothetical case of the child being bully, see Table 4). The first factor consisted of 3 items and measures outwards-oriented coping. The second factor consisted of 2 items and measures child oriented coping (in terms of exerting or not punishment and self-blame) and the third factor (2 items) measures inwards-oriented coping. In this subscale, parents adopt different strategies in the hypothetical case of their child being a bully, since they tend to focus on inwards oriented and child oriented coping.

Table 4. Factor analysis of parental coping (hypothetical case of the child as a bully)

	Factors		
	I	II	III
Outwards-oriented coping ($\alpha = .52$, $M = .46$, $SD = .33$) I would talk with the bully's parents and I would inform them about the bullying incident.	.79		
I would talk with the bully's friends without blaming them.	.70		
I would talk with the school staff and I would inform them about the bullying incident.	.59		
Child-oriented coping ($\alpha = .36$, $M = .80$, $SD = .31$)			
I would punish him/her.		-.79	
I would talk with him/her trying to explain what is wrong, without blaming him/her		.76	
Inwards-oriented coping ($\alpha = .03$, $M = .83$, $SD = .25$)			
I do not like bullying, but it is none of my business to deal with it.			-.80
I would try to solve any family problems that might have an impact on my child's behavior.			.57
Eigen value	1.70	1.23	1.05
% of the total variance	22.79	17.54	15.5

5) Questionnaire on Parenting Practices

The parenting practices were measured with a 20-item self-report scale comprising of three factor-analytically derived subscales, according to the theoretical model by Baumrind (1991): authoritative, permissive and authoritarian practices. The parents answered these items on a four-point Likert scale, ranging from “does not apply at all” to “it applies always” (See table 5). One item of the scale was excluded because it had low loadings on the factors.

Table 5. Parenting practices

	Factors		
	I	II	III
Authoritative practices ($\alpha = .75$, $M = .93$, $SD = .14$)	.74		
I am interested in my child's school behavior.			
I am interested in my child's school achievement.	.72		
I respect my child's views and I encourage him/her to express them freely.	.72		
When my child misbehaves, we have a nice talk about it.	.65		
I believe in the children's rights.	.60		
I get a lot of satisfaction from my child.	.57		
I try to help my child, when teased by his/her friends.	.54		
I usually take into consideration my child's wishes and choices when planning for the family.	.54		
We share warm, intimate moments with my child.	.47		
I believe that children have a right to make decisions about their future.	.43		
Permissive practices ($\alpha = .43$, $M = .13$, $SD = .20$)			
Most of the people I know would say that I am very tolerant when my child misbehaves.		.68	
I punish my child when he/she misbehaves less than other parents.		.65	
I tend to spoil my child.		.49	
There is a lot of tension between me and my child.		.33	
Authoritarian practices ($\alpha = .41$, $M = .53$, $SD = .26$)			
I would not allow my child to question any of my decisions.			.73
I believe that children are immature and are not capable of making decisions for themselves.			.52
I believe that nowadays, parents recognize a lot of children's rights, and this spoils them.			.44
I apply strict rules to discipline my child.			.41
I am really worried if everything is okay, when my child is away.			.36
Eigen Value	3.83	1.66	1.57
% of the total variance	20.14	8.72	8.25

RESULTS

The data are presented in two sections. The first section presents the descriptive characteristics of the participating parents in relation to a) their views regarding bullying frequency b) their views as regards the coping strategies their children adopt, c) the coping strategies they recommend to a child who is being bullied d) their coping strategies in both hypothetical cases (child as a victim and child as a bully) as well as descriptive characteristics of parenting practices. The second section presents the correlations between parenting practices and parenting coping strategies, namely (a) children's coping according to parents' views, b) coping strategies that parents recommend to a child being bullied and c) parents' coping in the hypothetical case of their child being a victim or bully.

1. Descriptive Characteristics of Parental Views Regarding Bullying Frequency, Coping, and Parenting Practices

Experience of Bullying According to the Parents' Views

15.3% (n= 172) of the participating parents stated that their children had been bullied at school, 20.9% (n=236) stated their children were bullies, 16.7% (n=188) stated their children were bully-victims, while 47.1% (n=531) responded that their children had not been involved in any bullying experience either way (Table 6).

Table 6. Frequency of bullying experience according to parents' views

		Child as a bully		
		Never	Seldom-often	Total
Child as a victim	Never-seldom ¹	Group 3 531 (47.1%)	Group 2 236 (20.9%)	767 (68.1%)
	Often-very often	Group 1 172 (15.3%)	Group 4 188 (16.7%)	360 (31.9%)
	Total	703 (62.4%)	424 (37.6%)	1127 (100%)

Parents reported verbal bullying as being most frequent (66%), followed by social exclusion (49.7%), *physical bullying*, (47.5%), spreading rumors (34%), *attack on property* (28.1%), threats (10.8%) and *racist* forms of verbal bullying (9.8%) (See Table 7).

Coping Strategies of Bullied Children According to Parents' Views

According to parents, the strategies their bullied child use are mainly disclosure ($M = .66$, $SD = .22$), followed by approach-problem-focused coping ($M = .14$, $SD = .20$), and avoidance ($M = .12$, $SD = .21$). Although the sex of the bullied children did not differentiate the three factors of the scale, girls have been found to adopt the following strategies significantly more, in

¹The group of bullied children according to their parents was separated in a) being bullied often or very often versus seldom or never being bullied. This has been adopted since there were small numbers in the categories: never, versus seldom, often and very often. On the other hand, the group of bullies was separated in a) never being involved in bullying versus b) bullying seldom, often and very often.

comparison to boys, according to their parents' views: "Tells about it to siblings" ($X^2(1)=6.271$, $p=.008$), "Bursts into tears" ($X^2(1)=3.162$, $p=.047$) and "Avoids the bullying situation" ($X^2(1)=10.456$, $p=.001$). A small percentage of parents (6.6%) stated that they were not aware of their bullied child's coping, which was significantly higher for the parents of bullied boys, in comparison to those of bullied girls ($X^2(1)=5.358$, $p=.015$).

Table 7. Frequency of bullying experience according to parental views (children as victims and bullies)

		Children as victims					Children as bullies			
		Never	Seldom	Often	Very Often		Never	Seldom	Often	Very often
Verbal bullying	<i>n</i>	383	517	183	44		907	194	22	4
	%	34.0	45.9	16.2	3.9		80.5	17.2	2.0	0.4
Social exclusion	<i>n</i>	567	402	129	29		905	202	17	3
	%	50.3	35.7	11.4	2.6		80.3	17.9	1.5	0.3
Physical bullying	<i>n</i>	595	400	107	25		965	140	20	2
	%	52.8	35.5	9.5	2.2		85.6	12.4	1.8	0.2
Spreading rumors	<i>n</i>	744	298	74	11		1031	86	9	1

Recommended Parental Coping Strategies for a Child Being Bullied

The parents stated that when a child is being bullied, the first coping strategy she/he should choose is disclosure ($M=.93$, $SD=.11$), followed by avoidance ($M=.58$, $SD=.29$), and retaliation ($M=.36$, $SD=.21$).

Parental Coping Strategies for Bullied Children and Bullies

As previously stated, parents tended to focus on strategies oriented toward the inward, private family life when given the hypothetical situation of their child being a bully ($M=.83$, $SD=.25$). This was followed by strategies directed at a child ($M=.80$, $SD=.31$) and the last choice were strategies directed outwards, making the bullying situation public ($M=.46$, $SD=.33$). This was in stark contrast to the hypothetical case of their child being bullied: then parents tended to adopt strategies directed mainly outside the family ($M=.79$, $SD=.28$), in comparison to the inward strategies ($M=.53$, and $SD=.29$).

Parenting Practices

Overall, the majority of parents stated that they would mainly use authoritative practices, ($M=.93$, $SD=.14$), followed by authoritarian ($M=.53$, $SD=.26$) and lastly permissive ($M=.13$,

$SD=.20$). Significantly more mothers than fathers stated that they exert authoritative practices (Mann-Whitney $z = -2.862$, $p < .05$).

2. Associations between Parenting Practices and Coping

Parenting Practices and Bullying Experience

Authoritative practices were negatively associated with threats ($\rho = -.077$, $p < 0.01$) and racism as forms of verbal bullying ($\rho = -.091$, $p < 0.01$). Authoritarian parenting practices significantly correlated to verbal bullying ($\rho = .075$, $p < 0.05$), spreading rumors ($\rho = .080$, $p < 0.01$) and threats ($\rho = .086$, $p < 0.01$). Lastly, permissive practices were significantly associated with all forms of bullying, except damaging objects (Table 8).

Correlations between Parenting Practices, Bullied Children's Coping according to their Parents and Recommended Coping when a Child Is Being Bullied

In accordance with parental views, avoidance as a coping strategy adopted by the bullied children correlated significantly to permissive practices ($\rho = .069$, $p < 0.05$), whereas disclosure correlated significantly to authoritative practices ($\rho = .106$, $p < 0.01$) (see Table 8).

Table 8. Correlations between parenting practices, bullied children's coping according to their parents and recommended parental coping when a child is being bullied or bullies.

	<i>M</i>	<i>SD</i>	Authoritative (<i>M</i> =.93, <i>SD</i> =.14)	Authoritarian (<i>M</i> =.53, <i>SD</i> =.26)	Permissive (<i>M</i> =13, <i>SD</i> =.20)

Outwards- oriented	.46	.33			

** Correlation is significant at the 0.01 level (2-tailed).

*Correlation is significant at the 0.05 level (2-tailed).

Retaliation and avoidance as coping strategies that the parents recommend to a child being bullied were significantly associated with permissive practices ($\rho = .121$, $p < 0.01$ and $\rho = .079$, $p < 0.01$ correspondingly). Disclosure as a coping that the parents recommend to a child being bullied was associated with authoritative practices ($\rho = .133$, $p < 0.01$) (see Table 8).

Parents whose Children Are Bullied vs Children who Are not Involved

Following these analyses, we wanted to look at the parents whose children had been bullied and to compare their coping strategies to those parents who stated that their children were not involved in bullying. The results showed that the former recommended significantly more retaliation and avoidance as coping practices than the latter (see Table 9)

Table 9. Coping and child as victim: Means (SD) and statistical significance

DISCUSSION

A number of studies have pointed to the link between family relationships and bullying in terms of both its inception and duration (e.g., Bowers et al., 1994; Olweus, 1993). Notwithstanding, researchers have only recently started to pay attention to the role of family in the bullied victims' coping process (see Espelage & Swearer, 2003; Smith, 2004). The main focus of our research was to examine coping strategies parents propose to their children in order for the latter to deal with being bullied. These results cannot be compared directly with the coping strategy ratings obtained in other studies (e.g., Smith *et al.*, 2001), due to the fact that not only did the researchers of the present study use different coping strategies, but also because in the majority of other studies children rather than parents have been used as the main informants. However, with some caution, some comparisons can be discussed.

Experience of Bullying According to Parents' Views

Although the frequency and distribution of bully-victim status types was not the major objective of our study, we feel however that they are important and deserve at least a brief comment. According to the parents' views, bullying is perceived as being an extensive problem in Greek schools, since in the study, a high percentage of children were stated as being or having been involved as victims, bullies and bully/ victims. These data replicate the results of other international studies and call for for effective anti-bullying interventions, that also include the role of parents (Due et al., 2005). An interesting finding of the present study is that just over a fifth of the students were stated by the parents as being bullies (20.9%), compared to 15.3% who were claimed to be victims. It could be that when students participate as informants they are less willing to disclose their status as a bully, as they may be afraid of the negative consequences that this could have (Alsaker & Valkanover, 2001). Another explanation for the high percentage of bullies as stated by the parents, might be due to methodological factors; in our study children were defined as bullies when they were both seldom and often

involved in a bullying incident as opposed to those not involved at all. While the victims were classified as being or having been bullied often or very often as opposed to the not involved who had seldom or never been bullied.

In addition, in the present study only a small percentage of parents—mainly those who had boys—reported not being aware of their children's coping strategies when bullied. Overall, our findings contradict the main literature that talks about high parental underestimation of bullying. For example, Fekkes et al. (2005) found that nearly half of the parents of victims did not know that their children were bullied. Research suggests that this parental unawareness is the rule, rather than an exception (Rigby & Barnes, 2002; Smith, 2000). This lack of parents' being informed of their children's experiencing bullying is discussed in the literature as a significant risk factor: obviously if a parent does not know about his/her child being involved in bullying, he/she cannot support them. In fact, there is evidence to suggest that even when they know that their children are being bullied, parents often fail to support and protect them (Sawyer et al., 2011). It is granted that theoretically at least, parents can either overestimate or underestimate bullying. The present study based only on parental self-reports is quite unlikely to answer this binary tendency, though it does provide some evidence that parents are in fact informed about bullying incidence by reporting its frequency to a comparable degree to that usually reported by children (e.g., Forero, McLellan, Rissel, & Bauman, 1999). Studies that seek information dynamics related to bullying, such as child-parent discrepancy need to investigate data from both parents and children.

Verbal bullying was the most common form, a finding that is confirmed by many studies (Skrzypiec et al., 2011). Verbal bullying is usually underestimated in terms of its impact on children's well being and needs to be addressed in a more systematic way.

Bullied Children's Coping Strategies (Parental Views)

According to the parents who participated in the present study, when their child was bullied, she/he tended to cope with the situation by disclosing the incident to them (Mean .66), followed by the approach/problem-focused approach (Mean .14), whereas the findings show that avoidance was the least chosen option (Mean .12).

We would like to note that from the factor analysis, Approach as a coping strategy included practices like "Avoids the bullying situation" or "asks for revenge". In other words, parents seem to consider these ways as belonging to the same line of practices such as taking precautions, or asking the bully to stop their behaviour. Furthermore, the parents' conceptualization of their bullied children's avoidance strategy, is mainly seen as them adopting internalizing ways of coping, such as crying and hiding away, along with the child's refusal to attend school.

Although there is rich literature regarding children's coping strategies, most of the studies use the children as the main informants. For example, Smith *et al.* (2001) in England investigated coping strategies used by 10- to 14-year-old victims of bullying (similar age group to that used in our study). According to their study the most common coping strategies used by the students were "ignored the bullies", followed by "told them to stop", "asked an adult for help" and "fought back"; the least used coping strategies were "ran away", "asked friends for help", and "cried".

Consistent with the literature researching children's coping (Causey & Dubow, 1992), in the present study, children typically prefer "disclosure" strategies as a way to their dealing with bullying. Avoidance was the strategy least preferred by the children. The items "bursts into tears", "runs away" and "refuses to attend school" used in the present study, are also classified as *internalizing strategies* and have been associated with anxiety and peer victimization (Causey & Dubow, 1992; Kochenderfer-Ladd & Skinner, 2002). According to the international literature, passive strategies, overall, have been linked with repeated victimization and negative psychological consequences. Still, it is important to note that these behaviors are often antecedents as well as consequences of victimization and thus children become involved in a vicious cycle of repeated victimization (Singh, & Bussey, 2009).

Recommended Parental Coping Strategies to a Child Being Bullied

Looking first at the overall preference for the different coping strategies, Disclosure emerged as the most recommended or preferred coping strategy, followed by Avoidance; least preferred was Retaliation. There are studies that indicate disclosure as an effective coping mechanism. For example, Smith and Shu (2000) found that 55% of pupils bullied who disclosed it to adults (teachers or parents) reported that things improved or were cleared. Generally, researchers and school staff encourage pupils to tell someone if they are being bullied and are unable to deal with the situation on their own (Smith, et al., 2001; Tsiantis, et al., 2007). This is also the prominent theme in national anti-bullying campaigns in Greece, encouraging the students who have or are suffering bullying, to seek social support by disclosing their experiences (Tsiantis et al., 2007). On the other hand, "telling" can have negative connotations-mainly for older children- and hence may hinder them from seeking social support when in fact they greatly need it (Rigby & Bauman, 2010).

In other words, the participating parents would recommend to a child being bullied, first disclosure (Mean .93), followed by avoidance (Mean .58) and retaliation last (Mean .36). That is, disclosure was not only indicated as the bullied children's favorite coping, but the most recommended one by parents.

Interestingly, in the factor retaliation, "help seeking from friends" is also included. In the literature about coping and bullying, help seeking is a form of social support that is usually classified as a positive way of managing the bullying situation. However, according to the parents' understanding in the present study, help from friends as part of the broader factor of retaliation might be seen as a way that the bullied child can take revenge on those who are bullying her/him by calling on the strength of numbers of friends.

In general, in the present study, the parents would noticeably recommend more network support such as disclosure than the coping of avoidance and retaliation. However, Matsunaga (2010) points out that disclosure as a kind of support might be considered by bullied victims as undesirable, since bullied children strongly fear that their status as victims will eventually be known by others (Fekkes et al., 2005; Rigby & Barnes, 2002).

The majority of the parents in the present study have avoided retaliation as a recommended parental coping. This is very encouraging since retaliation has been found inadequate for solving bullying overtime. For example, Salmivalli et al. (1996) in Finland found that "counter-aggression" in bullied children was a behavior associated with initiation or continuation of

bullying. Children need to avoid strategies associated with increased victimization and psychological maladjustment. In addition, retaliation is classified as an externalizing way of coping (Singh & Bussey, 2009) which involves students in negative peer interactions and potentially can lead them to employ aggressive strategies as a way of avenging the victimization they have experienced. This seems to be recognized by the parents in the present study, since the retaliation has been least recommended.

Parental Coping Strategies in Relation to the Bully Status: Victim vs. Bully

In the hypothetical case of their child being either bullied or a bully, the parental coping strategies were similar to a degree in the way that in both cases, they tended to favor an approach or problem- focused way of coping, based mainly on talking about the bullying and seeking help. At the same time, however, the strategies were quite distinct: in the case of a bullied child, the parents seem to opt for a solution outside the family and/or the close circle of the child's friends. They feel the problem lies with the bullies or the school setting where the bullying behaviour takes place. Consequently, the parents state that they would rather inform the school or the bully's parents in order to solve the problem and put an end to their children's distress (outwards-directed coping, *Mean* .79 versus inwards-directed coping, *Mean* .53). It is as if parental attributions are in a way liaised with an external focus of control.

On the other hand, things seem to change radically in the hypothetical case of their child being a bully. In this situation, the first choice for parents is to search for solutions within the family (*Mean* .83) and, second, they favor an individual-tailored approach toward the bully (*Mean* .80); they would definitely, avoid asking for help from the schools or the other parents (*Mean* .46) (e.g., the bullied children's parents). Many reasons may be attributed to this kind of parental attitude: many parents feel ashamed or embarrassed of their child's behaviour; they may be apprehensive the school staff will blame them for their child's bullying behaviour (Bibou, et al., 2012); or they may believe that it is the child's or the family's role and responsibility to change and put an end to the bullying (Dowling & Osborne, 2004). Besides, there is evidence to suggest that schools have difficulty in collaborating with the families of the bullies (Tsiantis et al., 2007).

Furthermore, a promising outcome that arises in the present study in regards to parental coping is that they are least likely to blame either the bully themselves or the bullied child's friends for the bullying incident. The various attributions that students make as to the reasons for their victimization are well known and self blame is one of them. For example, Graham & Junoven (2001) found that bullied children who attribute their experience as a personal attack and who feel they themselves are to blame, are more likely to suffer from psychological difficulties. In addition, Singh & Bussey (2009) found that students with greater self-efficacy for avoiding self-blame are less likely to suffer psychological maladjustment than those whose self-efficacy beliefs were lower. The findings on bully-victim status differences in parental coping strategies contribute to a growing literature on variations in coping strategies in response to bullying. More evidence is still needed on the effectiveness of different coping strategies. In addition, more studies are required to examine how parental coping varies with person and context variables. We believe that observational and longitudinal studies will contribute most to this.

Following on from the main analyses, we make a comparison of parents whose children fall in either of the following two groups: children who according to their parents have been bullied (even if seldom) as opposed to those who, again according to their parents, have never been involved in bullying. It is cause for concern that significantly more parents whose children had suffered bullying incidents, recommended retaliation and avoidance as coping practices, in comparison to the other group of parents whose children had not experienced bullying episodes. This finding is in to an extent consistent with research which has shown that passive coping is more prominent in children who have been bullied when compared to those who have not (Olweus, 1993; Schwartz, Dodge, & Coie, 1993). Nevertheless, the fact that the previous studies are based on students' self-reports needs to be kept in mind when relating the data to the present research. Although the parents in our study, might have recommended these particular strategies as a way to put an end to their children being bullied, it cannot be ignored that these same strategies have been associated with an increase in psychosocial difficulties and the perpetuation of the bullying behaviour (Mahady-Wilton et al., 2000; Cowie, 2004).

A comparison was also made of the parental coping strategies where according to the parents: a) the children have been bullies (whether often or seldom), b) the children have never been involved in bullying. It is promising to note that the parents who described their children as being bullies stated that the coping strategy they would propose is more child oriented than the other group of parents, whose children were not involved in bullying behavior. In other words, the parents of bullies would choose to talk to their children in order to find out and understand what the problem was rather than use punishment as reprimand for wrong-doing.

Parenting Practices, Experience of Bullying and Coping

In the present study, authoritative practices were the first choice of parents, followed by authoritarian and permissive practices. Our findings appear to be consistent with the literature on the association of parenting and aggression in general (Barry et al., 2009; Idsoe et al., 2008; Ybarra & Kimberly, 2004) which more specifically states that the more the parents use permissive practices, the more they report that their child is being bullied at school. In other words, when parents use permissive practices, there is a higher incidence of the children being bullied at school. In fact, this has been also validated by the association between the authoritarian parenting and some forms of bullying (verbal bullying, spreading rumors, and being threatened) in our study. Authoritative practices, on the other hand, have been related with the absence or a significant reduction in some forms of bullying such as threats and racism.

Regarding the relationship between parenting and coping strategies, it appears that the more permissive the parents were in their children's upbringing, the more their bullied children tended to use avoidance as a way of coping with bullying. Furthermore, permissive practices were associated with retaliation and avoidance as parental coping strategies recommended to a child being or having been bullied. Lastly, in the hypothetical case where the child was a bully, there was a negative relationship between parental authoritarian practices and inwards-directed coping, in the hypothetical case of the parents' child being a bully. That is, the stricter the parents, the less they would use inwards-directed coping. Authoritative practices, on the other hand, were highly related to disclosure as a way the bullied child attempts to deal with bullying and as a way the parents recommend to a child being bullied. That is, the more democratic the parents, the more they would choose or would recommend to a bullied child to talk about the

incident and try to come to a solution together. This is explained by the fact that authoritative parents believe in the communicative and relational dynamics of disclosure interactions. A family context that promotes emotional support, setting rules and interactional communication predisposes the disclosure of one's bullying experience of bullying (see, e.g., Greene, 2009). Bullied victims –according to research review- could make disclosure decisions based not only on their own inclination, but also with regard to the willingness of the given interactional partner to listen to them. Naturally, victims would be discouraged to talk about their bullying experiences if their parents were incapable of managing what the child was going through; or even in the more negative reactions of punishing, blaming or even showing disengaged attitudes to the bullied child (Mishna, 2004).

In the hypothetical case of their child being a bully, the parents who use authoritative practices tended to choose strategies that were inwards-directed coping and coping oriented to the child. That is the more authoritative were the parental practices for their children's upbringing, the more they would opt for helping their child who was a bully avoid both blaming the child and by reflecting on the family's functioning.

In considering the results of the study, certain methodological issues need to be taken into account. First, the questions asking parents what ways they would react in response to different types of bullying are hypothetical. Presumably, parents who had the experience of a bullied child responded to these questions with the coping strategies they had in fact used at the time. Alternatively, one could support the view that these parents may have responded to these questions by using totally different coping strategies from the ones they had actually used should their original coping strategies have failed to reduce or eliminate their children's being bullied at the time. As a result, the coping strategy responses given by the parents are merely considered representations of what a) their bullied children would do in the various bullying situations, and b) their own coping strategies whether these were recommended or had been chosen at an earlier time.

Second, in terms of the data collection, the results are based on parental self-reports only. There is a need to correlate these findings with the children's responses and the teachers' views regarding parental coping strategies (Taber, 2010). On the other hand, many researchers (for example, Mizell, 2003), have found the parental views reliable since they closely related to the views of other informants such as teachers.

Third, parenting practices are also based on self-reports only and should be expanded by the children's views on parenting practices. According to Stevens et al. (2002), children usually evaluate parenting practices more negatively in comparison to the parents themselves. However, the particularly permissive or authoritarian parenting practices are very likely to be a contributory factor in the predicament of these children, who generally fare worse on measures of psychosocial adjustment (Baldry & Farrington, 2005).

Fourth, It should be noted that some of our results should be interpreted with caution, since some measures of parental coping fell below the generally accepted level for internal reliability of scale items (Henson, 2001). More specifically these were: in the case when the child was being bullied, the choice for outwards-directed parental coping strategies; and in the case were the child was described as a bully, the choice for inwards-directed parental coping strategies. Future research should endeavor to develop or use psychometrically stronger scales to assess these constructs.

Implications of the Study

When it comes to researchers' suggestions as to how we can counteract the issue of bullying, there does not seem to be simply one way to approach the problem. Indeed, when researchers introduce their ideas on how to eliminate bullying, they commonly propose a combined set of anti-bullying interventions, many of which often aimed at improving the victims' coping strategies (Cowie & Sharp, 1994; Smith et al., 2001). The idea is that victims who have more effective ways of dealing with bullying situations, for example by ignoring the bully, assertively asking the bully to stop, or seeking help from a friend or adult, may be able to put a stop to the bullying at an early stage (Salmivalli et al., 1996; Smith & Shu, 2000). The present study investigated parental views regarding coping with bullying, since parents are significant models for teaching their children how to cope with stressful situations. We believe that these findings provide evidence on the necessity of parents being willing to help and emotionally support their bullied children and in doing so play an active part in anti-bullying practices.

Taking parental views into consideration could lead to effective promotion and intervention of anti-bullying programs. In addition, teachers' awareness of parental views might enhance home-school collaboration for better managing bullying (Eslea & Smith, 2000; O'Moore & Minton, 2004; Orpinas & Horne, 2006). The closer the parental communication with the school staff, the more effective are anti-bullying plans and programs (Sheridan et al., 2004).

ABSTRACT

Bullying among children and adolescents is a common, detrimental behavior that can impact an individual and community at multiple levels. Researchers define bullying as repetitive, intentional attacks (physical or psychological) that cause harm to a victim, in the context of a power imbalance. Numerous factors modify the likelihood of becoming a bully, a victim or a combination bully/victim. These include risk factors present in youths themselves, in their families, schools, and communities. Similarly, protective factors have been identified and preventative interventions based on identifying and strengthening these factors have been developed. Bullying experiences may negatively impact the psychosocial well-being of both bullies and victims. Moreover, bullying has been associated with academic difficulties and negative consequences for physical and mental health. The consequences of bullying may be long term and even fatal, given that bullies and victims are at a higher risk for suicide. Numerous treatment strategies to diminish the negative impact of bullying have been implemented. Most evidenced-based interventions are preventative programs through the school system; however, individual interventions can include mental health evaluations as well as family interventions. In schools, the most beneficial interventions to decrease victimization include parent/teacher meetings, disciplinary methods, and increasing the duration and intensity of the program for both children and teachers. In this chapter, we review risk and protective factors, explore how bullying may impact psychosocial and physical well-being, and discuss up-to-date

treatment strategies to help clinicians recognize and decrease the impact of bullying in childhood and adolescence.

INTRODUCTION

Research into bullying began in the early 1970s in Scandinavia and expanded throughout the world in the 1980s and 1990s. Over the last decade, there has been tremendous growth of American research on the topic of bullying. Bullying is the most common form of school violence. In their landmark study of the prevalence of bullying behaviors in the United States, in 2001 Nansel et al. found that up to 29.9% of students in grades 6 through 10 reported being involved in moderate or frequent bullying: 13% were identified as a bully, 10.6% as a victim, and 6.3% as a bully-victim, which is an individual who has experienced bullying victimization and perpetration. (Nansel, Overpeck, Pilla, Ruan, Simons-Marto, & Scheidt, 2001) A smaller study more recently found that about 22% of students reported being involved in bullying: 6% as bullies, 14% as victims, and 2% as bully-victims. (Glew, Fan, Katon, Rivara, & Kernic, 2005)

Studies from around the world demonstrate a high prevalence of bullying experiences among school-aged youth. Kumpulainen et al. (1998) found that 8.1% of Finnish children were identified as bullies, 7.6% as victims, and 11.3% as bully victims. In an Australian study 57.8% of students reported involvement in bullying: 23.7% identified as bullies, 12.7% as victims, and 21.5% as bully-victims. (Forero, McLellan, Rissel, & Bauman, 1999) Among South Korean middle school students, 40% reported involvement in bullying with 17% identified as bullies, 14% as victims, and 9% as bully-victims. (Y. Kim, Koh, & Leventhal, 2005) Interviews of students and parents in India found that 31.4% of children were involved in bullying. (Kshirsagar, Agarwal, & Bavdekar, 2007) In South Africa, 36.3% of students reported involvement in bullying: 8.2% as bullies, 19.3% as victims, and 8.7% as bully-victims. (Liang, Flisher, & Lombard, 2007)

As the significance of bullying has been recognized, research in bullying continues to expand and examines many different factors related to bullying, including predictors or risk factors, consequences and sequelae of involvement with bullying, as well as development and evaluation of bullying prevention programs. While there are variations in the definition of bullying behavior, researchers and clinicians have generally agreed on the definition created by Dan Olweus, an early and preeminent researcher in the field, who noted, "A student is being bullied or victimized when he or she is exposed, repeatedly and over time, to negative actions on the part of one or more other students." Another key factor is that an imbalance in strength or asymmetric power relationship is present. (Olweus, 1994) Accordingly, bullying may be defined as repetitive, intentional attacks (physical or psychological) that cause harm to a victim and occur in the context of a power imbalance. Direct bullying includes physical aggression (e.g., hitting, pushing, kicking, locking in a room, being forced to do things, having money/things taken away or damaged) and verbal aggression (e.g., name calling, teasing in a hurtful way, threats of violence). Manipulative behaviors in relationships, such as spreading rumors, social exclusion, manipulation of relationships, and friendship betrayals, may be considered forms of indirect bullying.

Changes in use of communication technology have allowed for the growth of a new type of bullying behavior that is has been termed "cyberbullying". Cyberbullying is understood as

“willful and repeated harm inflicted through the use of computers, cell phones, and other electronic devices”. (Hinduja & Patchin, 2010) Cyberbullying may be a significant contributor to overall bullying experiences in the US, with at least one study finding rates of perpetration between 9.1% and 23.1% and victimization between 5.7% and 18.3%. (Hinduja et al., 2010) Three distinct status groups differentiate youth involved in bullying: individuals who are victims only (victims), individuals who are bullies only (bullies), and victimized individuals who also bully (bully-victims). This chapter will provide an overview of risk and protective factors, explore how bullying may impact psychosocial and physical well-being, and discuss up-to-date prevention strategies.

PREDICTORS OF INVOLVEMENT IN BULLYING

Many studies have examined not only the risk factors for becoming a victim, but also the risk factors for becoming a bully or a bully-victim. Overall younger age is one risk factor for involvement in bullying, especially status as a victim. (Liang et al., 2007; Olweus, 1994) Olweus noted that the percentage of students being bullied decreased with higher grades. (Olweus, 1994) He also found that as children progressed in age, there was a trend towards decreased use of physical means of bullying. (Olweus, 1994) Male gender has been found to be another risk factor for involvement in bullying. (Cook, Williams, Guerra, Kim, & Sadek, 2010; Liang et al, 2007; Olweus, 1994) Boys were found to be exposed to bullying more often than girls, especially in regards to direct bullying. (Olweus, 1994) Similar findings were noted in other studies with more males involved in bullying than females. (Y. Kim et al., 2005; Nansel et al., 2001) However in India it was noted that there was no significant differences in bullying between males and females at co-ed schools, but the rate at all girl schools was significantly low. (Kshirsagar et al., 2007) In Australia, males were more often found to be bullies or bully-victims, whereas slightly more females identified as victims than males. (Forero, McLellan, Rissel, & Bauman, 1999) Olweus did find girls and boys to be equally exposed to indirect forms. (Olweus, 1994) There is also some evidence that when girls are involved as bullies they are more impaired. (Y. Kim et al., 2006; Klomek, Marrocco, Kleinman, Schonfeld, & Gould, 2007; Klomek, Sourander, & Gould, 2010) For instance, Kim et al. (2006) found that when compared to male students, female students who became bullies were at greater risk of developing externalizing problems and females who developed externalizing problems were at greater risk for becoming bullies. Sexual orientation has also been associated with risks of involvement in bullying. While gay males were less likely to be identified as a bully than heterosexual males, mostly heterosexual and bisexual females were found to have an increased risk of being identified as a bully when compared to heterosexual females. (Berlan, Corliss, Field, Goodman, & Austin, 2010) When it comes to victim status, mostly heterosexual males and females, gay males, lesbian females, and bisexual females were all more likely to be victims than their heterosexual counterparts. (Berlan et al., 2010)

Overall, status as a **victim** has been associated with many qualities such as physical weakness, depression, and anxiety. (Fekkes, Pijpers, & Verloove-Vanhorick, 2004; Fekkes, Pijpers, Fredriks, Vogels, & Pauline, 2006; Olweus, 1994; Schwartz, 2000; Veenstra, Lindenberg, Oldehinkel, DeWinter, Verhulst, & Ormel, 2005) Victims also have less assertive-prosocial behaviors and are more withdrawn-submissive than uninvolved children. (Fekkes et

al., 2004; Olweus, 1994; Schwartz, 2000; Veenstra et al., 2005) They have also been found to have less social acceptance. (Schwartz, 2000) One study, however, found the association between social problems at baseline and victim status disappeared when baseline bullying status was adjusted for. (Y. Kim et al., 2006) In the United States, there is some evidence that status as an immigrant lead to an increased risk of being a victim. (Hepburn, Azrael, Molnar, & Miller, 2012) *Bullies* (nonvictimized) have been found to have high levels of aggressive and impulsive behaviors. (Kumpulainen & Rasanen, 2000; Perren & Alsaker, 2006; Schwartz, 2000; Veenstra et al., 2005) Social and environmental factors have also been found to be related to status as a bully, including exposure to domestic violence, problems with neighbors, parental conflict, and family dissolution. (Bowes, Arsenaault, Maughan, Taylor, Caspi, & Moffitt, 2009; Jablonska & Lindberg, 2007; Spriggs, Iannotti, Nansel, & Haynie, 2007) *Bully-victims* carry some of the risk factors of both bullies and victims. While they have been found to have high levels of aggression, they have also been found to have high levels of depression. (Perren & Alsaker, 2006; Schwartz, 2000; Veenstra et al., 2005) They also have been found to score low on measures of academic competence, prosocial behavior, and self-esteem. (Perren et al., 2006; Schwartz, 2000; Veenstra et al., 2005) The early history of these children also included abuse, harsh restrictive discipline, and exposure to domestic violence and parental hostility. (Schwartz, Dodge, Pettit, & Bates, 1997) Victims, bullies, and bully-victims have all been found to have increased amounts of early emotional and behavioral problems. (Ball, Arsenaault, Taylor, Maughan, Caspi, & Moffit, 2008; Schwartz, McFadyen-Ketchum, Dodge, Pettit, & Bates, 1999; Sourander, Helstela, Helenius, & Piha, 2000)

<i>Risk Factors for Bullying</i>
• High levels of aggressive and impulsive behavior towards peers. (Kumpulainen et al., 2000; Perren et al., 2006; Veenstra et al., 2005)
• Early emotional and behavioral problems. (Ball et al., 2008; Schwartz et al, 1999; Sourander et al., 2000)
• Socio-environmental factors such as domestic violence and problems with neighbors are associated with children' risk for becoming involved in bullying. (Bowes et al., 2009)
• Negative family factors like interparental conflict and family break up are positively associated with bullying involvement. (Jablonska & Lindberg, 2007; Spriggs, Iannotti, Nansel, & Haynie, 2007)
<i>Risk Factors for being a Victim</i>
• Tend to be physically weaker, more withdrawn, depressed, anxious, and also less prosocial than uninvolved children. (Fekkes et al., 2004; Veenstra et al., 2005)
• Early emotional and behavioral problems. (Ball et al., 2008; Schwartz et al., 1999; Sourander et al., 2000)
<i>Risk Factors for being a Bully-Victim</i>
• High levels of both aggression and depression, and they score low on measures of academic competence, prosocial behavior, and self-esteem. (Perren et al., 2006; Veenstra et al., 2005)
• Early emotional and behavioral problems. (Ball et al., 2008; Schwartz et al, 1999; Sourander et al., 2000)

Figure 1.

Given that bullying takes place in a social context, it is important to consider how contextual factors such as home environment and school culture impact bullying. A recently published meta-analysis assessed the strengths of individual and contextual factors in

predicting bully status (bully, victim, or bully-victim) across 153 studies that met criteria for inclusion. (Cook et al., 2010) The individual factors included: age, internalizing behavior, externalizing behavior, social competence, self-related cognitions (children's thoughts, beliefs, or attitudes about themselves), other-related cognitions (children's thoughts, beliefs, feelings, or attitudes), and academic performance. Contextual factors included: family/home environment, school climate, community factors, peer status (defined as the quality of relationships children and adolescents have with their peers), and peer influence. Strong individual level predictors of bully status included externalizing behavior ($r = .34$) and other-related cognitions ($r = -.34$). Victims had low peer status ($r = -.35$) and poor social competence ($r = -.30$). The strongest individual level predictors for bully-victim status were social competence ($r = -.36$) and self-related cognitions ($r = -.40$). Contextual factors were important predictors of involvement with bullying. For bullies, peer influence and community factors ($r = -.34$, $r = -.22$ respectively) were most important. For victims, peer influence ($r = -.35$), school climate ($r = -.16$), and community factors ($r = -.15$) had the largest influence. Peer influence was the most important contextual predictor for bully-victim status, with the remaining contextual factors except community factors being predictive.

Table 1. Predictor profiles of typical bully, victim, and bully-victim (Cook et al., 2010)

	Bully	Victim	Bully-victim
Individual predictors	Externalizing behaviors Internalizing symptoms Poor social competence Poor academic performance Negative beliefs about others Negative self-related cognitions Poor social problem solving	Externalizing behaviors Internalizing symptoms Poor social competence Negative self-related cognitions Poor social problem solving	Externalizing behaviors Internalizing symptoms Poor social competence Poor academic performance Negative beliefs about others Negative self-related cognitions Poor social problem solving
Contextual predictors	Poor family/home environment Negative school climate Negative community influence Negative peer influence	Poor family/home environment Negative school climate Negative community influence Rejected/isolated by peers	Poor family/home environment Negative school climate Negative peer influence Rejected/isolated by peers

In conclusion, individual and contextual risk factors for involvement bullying have been identified. These are largely related to the presence of affective problems, behavioral issues, and poor social skills. Much less is understood about contextual factors, given the relative paucity of research in this area compared to individual factors. Future efforts should focus on differentiating between the predictors of aggression and bullying and understanding how contextual factors interact with individual factors to predict bully status. Efforts should also be made to identify factors that lead to resilient youth or youth that “demonstrate the ability to

overcome and survive exposure to stress-related and adversarial conditions to lead normal and productive lives into adulthood.” (Donnon & Hammond, 2007) Donnan et al. noted 31 developmental strengths broken down into resiliency factors. These factors were parental support and expectations, peer relationships, community cohesiveness, commitment to learning at school, school culture, cultural sensitivity, self-control, empowerment, self-concept, and social sensitivity. (Donnon et al., 2007) Those with higher numbers of developmental strengths were less likely to be victims or bullies and those with the least amount of developmental strengths were the most likely to be either a victim or a bully. (Donnon et al., 2007)

CONSEQUENCES OF INVOLVEMENT IN BULLYING

Involvement in bullying is associated with a variety of health and social problems. Status as victim, bully, or bully-victim has been found to be associated with an increased risk of developing a variety of psychiatric difficulties such as internalizing and externalizing problems. It has also been associated with an increase in medical complaints, academic difficulties, and a variety other problems. While many of the initial studies were cross-sectional studies, emerging longitudinal studies support the association of bullying with multiple health and social difficulties. Studies have also begun to suggest that these difficulties can persist beyond the initial involvement as bully, victim, or bully-victim.

Internalizing Symptoms

Many cross sectional studies have shown an association between involvement in bullying and internalizing symptoms such as anxiety or depression. The evidence seems to be stronger for the association between depression and loneliness with victimization than anxiety. (Hawker & Boulton, 2000) However, increased rates of anxiety symptoms have also been associated with being a victim of bullying. (Bond, Carlin, Thomas, Rubin, & Patton, 2001; Hawker et al., 2000) Victims often have been found to have a higher risk of depressive symptoms than bullies or others not involved in bullying. (Bond et al., 2001; Kaltiala-Heino, Rimpela, Marttunen, Rimpela, & Rantanen, 1999; Kumpulainen et al., 1998; van der Wal, de Wit, & Hirasing, 2003) Evidence supports that bully status increases risk of depressive symptoms, although this is not consistent across studies. (Klomek et al., 2007; van der Wal et al., 2003) Bully-victims have been found to be the most disturbed and have the highest rates of depressive symptoms compared to bullies and victims. (Kumpulainen et al., 1998; Weiss, Mouttapa, Cen, Johnson, & Unger, 2011)

Many factors influence the strength of the association between involvement in bullying and elevated internalizing problems, including gender, frequency of bullying involvement, and type of bullying. (Bond et al., 2001; Klomek et al., 2007; van der Wal et al., 2003) Gender may moderate the risk of developing internalizing symptoms; Klomek et al. (2007) found that females with any frequency of bullying were at higher risk of internalizing symptoms but only males who frequently bullied were at higher risk. Similar findings have been noted for victims of bullying. Both boys and girls who were bullied indirectly were found to have a higher risk of depression and suicidal ideation. (van der Wal et al., 2003) However, when direct bullying

was examined, only girls who were sometimes and frequently bullied were found to be at elevated risk for depression and suicidal ideation. (van der Wal et al., 2003)

Longitudinal studies have demonstrated an increased risk of developing internalizing among victims of bullying. (Arsenault, Walsh, Trzeniewski, Newcombe, Caspi, & Moffitt, 2006; Fekkes et al., 2006) One study also found that the risk of internalizing symptoms is increased in bully-victims. (Arsenault et al., 2006) Other studies have attempted to discover the directionality of the relationship between bullying and internalizing symptoms, i.e., if bullying experiences lead to internalizing symptoms or if internalizing symptoms predisposed a person to be a victim of bullying. One study found evidence to support both theories. Individuals with anxiety and depression symptoms at baseline had an increased risk of being bullied over a one year period and victims of bullying had an increased risk of developing internalizing symptoms. (Fekkes et al., 2006) A meta-analysis of 18 studies also drew similar conclusion; the strongest evidence was that being a bully victim significantly predicted internalizing problems over time, but there was also evidence that internalizing problems could lead to being a bully victim. (Reijntjes, Kamphuis, Prinzie, & Telch, 2010)

There is growing evidence that there may be a long-term association between depression and bullying. Early studies found that students identified as victims in grades 6 to 9 had lower self-esteem and were more likely to be depressed at age 23 than control students. (Olweus, 1994) Sourander et al. found that frequent victimization among females predicted use of antidepressants and psychiatric hospital treatment. There was a similar pattern for victimized males when investigating medication use. Frequent bully-victim and bully status at baseline predicted any psychiatric medication, antidepressants, or anxiolytics and bully-victims status also predicted antipsychotic use. However, when adjusted for baseline psychopathology score, the status no longer predicted medication use. (Sourander et al., 2009) This study also found an increased rate of hospitalization for frequent male victims and frequent male bully-victims. However, the increased risk did not remain significant when adjusted for psychopathology score at age 8. (Sourander et al., 2009)

Suicidal Ideation and Suicide Attempts

Suicide is the third leading cause of death for young people in the United States. In addition to the increased risk of internalizing symptoms such as depression, there is evidence that involvement in bullying is associated with an increased risk for suicidal ideation and attempts. Cross sectional studies have shown an increased risk (odds ratio) of suicidal ideation or attempts related to bullying ranging from 1.4 to 10. (Klomek et al., 2010) The suicide risk has been found to be elevated for both bullies and victims. (Kumpulainen et al., 2000) Gender, frequency of bullying, and status have been found to influence the wide range of increase risk. (Kaltiala-Heino et al., 1999) Klomek et al. (2007) found that females with any involvement in bullying were at higher risk for suicide attempts and ideation. However, frequently bullied males demonstrated higher risk of attempts and ideation, infrequently bullied males had increased risk of attempts but not ideation, and males that frequently bullied others at higher risk of ideation but not attempts. (Klomek et al., 2007) The influence of gender on suicide risk is not consistent across studies. Some studies have shown increased risk for females, others for males, and still others have found no overall difference when gender is considered. (Klomek et al., 2010) A recent study with urban high school students showed that suicidal ideation and

attempts did not vary by immigrant status or gender. (Hepburn et al., 2012) In that study elevated risk of seriously considering suicide was found for bullies, victims, and bully-victims, but increased risk of suicide attempts was only noted for victims and bully-victims. (Hepburn et al., 2012) Many studies have found that the highest level of risk is associated with bully-victims, although at least one seemed to show that when depressive symptoms were taken into account, bullies had the highest odds ratio followed by bully-victims, then victims. (Kaltiala-Heino et al., 1999)

Increased risk of suicidality has also been found to be associated with bullying in longitudinal studies. In these studies the odd ratios have ranged from 1.7 to 11.8. (Klomek et al., 2010) The evidence is mixed, however, with some of the studies showing the association in males became non-significant after controlling for baseline depression. (Klomek et al., 2010)

Involvement in cyberbullying appears to increase risk of suicidal ideation and attempts. Hinduja et al. (2010) found that cyberbullying and cybervictimization increase risk for suicidal ideation and suicide attempt.

Externalizing Problems

Involvement with bullying has also been associated with an increase in externalizing problems, including difficulties in areas such as aggression, behavior problems like truancy and delinquency, and attention. A recent meta-analysis examined fourteen prospective studies on linkages between peer victimization and externalizing problems and found that peer victimization led to a significant increase in externalizing problems. In this study, externalizing problems at baseline also predicted increased peer victimization. (Reijntjes et al., 2011) Individual studies also show some interesting results. Elevated rates of externalizing problems such as aggression have been found in children identified as bullies, although at least one study suggested that this may not be consistent among all types of bullies. (Y. Kim et al., 2006; Kumpulainen et al., 1998; van der Wal et al., 2003) These authors found that while delinquent behavior was associated with participants that bullied others directly, it was not associated with children that bullied other peers indirectly. (van der Wal et al., 2003) Bully-victims also demonstrate elevated rates of externalizing behaviors and may have a higher risk compared to bullies and victims. (Y. Kim et al., 2006; Kumpulainen et al., 1998) Rates of externalizing symptoms have been found to be increased in bully-victims as young as 7 years old. (Arsenault et al., 2006) There is even evidence to suggest that at least in young children, female victims had higher rates of externalizing symptoms than control children. (Arsenault et al., 2006) Kim et al (2006) found that those youth identified as victims at baseline had increased risk of developing externalizing problems over a 10 month period.

There is also evidence that the association between externalizing behaviors and involvement in bullying may be persistent. One study found that children identified as bully-victims at 8 had increased rates of externalizing behaviors at 15 years old. (Kumpulainen et al., 2000) The same study noted that those who were bully-victims at 12 also had elevated rates of hyperactivity and other externalizing problems at 15. (Kumpulainen et al., 2000) While the rates were higher for bully-victims, bullies also continued to have elevated rates of externalizing symptoms at 15.

Health Problems

Psychiatric complications are not the only complications associated with bullying. Cross sectional and longitudinal studies demonstrate that bullying experiences are associated with health problems like headaches, abdominal pain, backache, sleeping problems, feeling tense, and bedwetting. (Fekkes et al., 2006; Gini & Pozzoli, 2009) A recent meta-analysis of cross sectional and prospective studies found increased risk for psychosomatic problems (i.e., headache, stomachache, backache, abdominal pain, dizziness, sleeping problems, poor appetite, bedwetting, skin problems, vomiting, feeling tired, feeling tense) in bullies, victims, and bully-victims. (Gini et al., 2009) In this analysis, bully-victims were at the highest risk for somatic symptoms, followed by victims then bullies. There is also some evidence that both bully and victim status is associated with use of medications for symptoms such as headache and difficulty getting to sleep. (Due, Hansen, Merlo, Andersen, & Holstein, 2007) The association of bullying and medical complaints may be long lasting, with at least one study finding that those who were bullied at twelve years old still had increased rates of psychosomatic symptoms at fifteen years of age. (Kumpulainen et al., 2000)

Other problems

Bullying experiences are associated with a variety of risk behaviors, social problems, and difficulties at school. Status as a bully-victim was found to be a risk factor that predicted smoking initiation. (Weiss, Mouttapa, Cen, Johnson, & Unger, 2011) Being a bully or a bully-victim has also been found to be associated with current smoking. (Forero et al., 1999) Alcohol use was found to be associated with status as a bully. (Nansel et al., 2001) Earlier studies found that 60% of those classified as a bully in grades 6-9 had been convicted of a crime by age 24 with an overall 4-fold increase in the level of recidivist criminal activity. (Olweus, 1994) Kumpulainen et al. found increased rates of school absenteeism in bully-victims and victims. (Kumpulainen et al., 1998) A more recent study demonstrated that while those involved in bullying were more likely to be suspended or expelled or to feel unsafe or as if they did not belong at school, they did not have a lower attendance than the control group. (Glew, Fan, Katon, Rivara, & Kernic, 2005) Poorer academic achievement has been associated with status as bully or bully-victim. (Nansel et al., 2001) Younger children identified as bully-victims have also been found to have lower academic performance and lower scores on reading tests. (Arsenault et al., 2006) Kim et al. (2006) found that children identified as victims at baseline only and persistent at baseline and at 10-month follow up were at increased risk for developing social problems.

Limitations

While the above-mentioned studies illustrate the growing body of evidence supporting associations between bullying and a wide variety of conditions, it is important to consider limitations in those studies. The preponderance of studies in bullying are cross-sectional and are designed to assess associations between variables. They, however, are descriptive and cannot answer questions about causation. The longitudinal studies attempt to clarify the

directionality of the relationship between bullying and problems, however “they do not allow for strong conclusions regarding causal relationships.” (Reijntjes et al., 2011) Another concern is that many of the studies used different informants to assess involvement in bullying. Some use peer nomination, some gathered information from teachers and parents, and others used self-identification. There is considerable heterogeneity in measures used to assess symptoms, and in terms and definitions. (Reijntjes et al., 2011) Finally, not all studies classify bullying experiences similarly; some use victim and bully status, whereas others categorize into victims, bullies, and bully-victims. Despite these limitations, the evidence supports that the potential consequences to involvement in bullying are serious and worthy of continued scientific enquiry.

INTERVENTION STRATEGIES

As discussed above, bullying is a widespread problem that affects elementary age-children up through young adults and beyond. Addressing bullying necessarily involves individual-level efforts, as well as broader interventions to impact social mores and behaviors in special populations, such as a schools or communities. In order to illustrate this fact, here is fictional case of bullying that represents a common scenario. John is a 13 year old boy who attends public middle school and is being harassed and teased by peers from school on his walk home. As the weeks go by, the harassment continues during school hours and escalates physically. The bullies start shoving John up against his locker and their threats increase in frequency and severity. John has a few friends in school who tell him to “deal with it” because they have been the target of these bullies in the past as well. John does his best to ignore the insults and physical attacks, but soon the bullies are sending him private messages that he should kill himself because no one likes him. Peers start defriending him on social media sites. Soon, John feels as though there is no reprieve from his torment. The harassment continues at home via his computer, on his walk to and from school, and continuously during school hours. How can this get better for John? Should the bullies be punished? If so, then how? Should John learn new coping mechanisms? Should John have individual counseling? Should John’s parents, his teachers, his neighbors, his community be included? The answer is yes to all of these questions. The treatment of bullying is no simple matter. Intervention strategies need to be intensive and focused on multiple aspects of a child’s life.

Before discussing intervention strategies, it is important to discuss appropriate expectations. The complete elimination of bullying is not feasible, and some aspects of bullying behaviors may be conceived of as developmentally normal. According to American Academy for Child and Adolescent Psychiatry (2011), it is expected that during the middle school to high school years a teenager’s developmental “job” is to individuate, find a group of peers, and separate emotionally from their parents. Therefore, separation of peer groups is necessary to help with a teenager’s self-identification. Some have argued that this separation and individualization is emphasized by pushing other peers out of a previous group, and this has been done with name calling, rumor starting, and other bullying-type behaviors. Although teens must develop their own identity during this time, it should be expected that this individualization can happen with mutual respect and without demeaning or putting down others.

Research into bullying prevention started in the early 1970s with Dr. Dan Olweus from Sweden. (Olweus, 2004) Over the past several decades, Dr. Olweus has continued his research and has compiled an extensive portfolio of evidenced-based treatments. He has also developed the most comprehensive anti-bullying program that is currently available for schools to adopt. The *Olweus Bullying Prevention Program* is designed for elementary through junior high schools (children aged 5-15 years old). It includes interventions at the individual, classroom, school, and community levels. Individual components include improved student monitoring, interventions at the time bullying occurs, holding meetings with students involved, and making individual interventions for those affected. Classroom components include involving the entire classroom in meetings, following a school wide set of rules, and involving parents when necessary. School wide components include establishing a Bullying Prevention Coordination Committee, administering a questionnaire annually to track improvements, and launching of the program in a school-wide event.

Since the *Olweus Program's* inception, over 40,000 students have participated and evaluated its efficacy. There have been reductions in bullying and victimization in the range of 20 to 70% in both peer and teacher ratings, overall disruptive behaviors in students have been reduced, and the culture in the school has been improved, as seen through more positive peer relationships, improved order and discipline, and better attitudes regarding schoolwork. Improvements are time-related based on age, the younger the students, the quicker the improvements occur. For instance, in grades 4-7 improvements can be seen within 8 months, however for students in grades 8-10, improvements may occur as late as two years after the program's adoption. The program, including an on-site coordinator, questionnaire, computer program, and teacher training can be purchased at www.clemson.com/olweus.

Since Dr. Olweus' conception of his program, research in intervention strategies has expanded, especially in the last 5-10 years. In an earlier meta-analysis, results were limited and there was concern that no programs caused meaningful change, positive or negative. (Merrell, Gueldner, Ross, & Isava, 2008) The analysis determined that anti-bullying campaigns were more likely to change attitudes, knowledge or awareness of bullying rather than actual bullying behaviors. Limitations of this analysis included strict inclusion criteria, leading to a small sample of sixteen studies. In a more recent meta-analysis, Farrington and Ttofi (2009) evaluated 622 reports of varying forms of bullying prevention. Of these numerous articles, 44 met their strict criteria of sample size (greater than or equal to 200) and controlled methodological criteria. The authors evaluated individual anti-bullying plans as well as looked at all of the plans as a whole to determine which specific elements were the most effective, or ineffective. Discussed below are individual programs deemed effective by the meta-analysis with a significant odds ratio of over 1.4.

School Psychiatric Consultation (SPC) and Creating A Peaceful School Learning Environment (CAPSLE) (Fonagy, Twemlow, Vernberg, Nelson, Dill, Little, & Sargent, 2009)

This experiment involved third to fifth graders in three different elementary schools over three years (two treatment years, one maintenance year). There were three arms in this study, treatment as usual (TAU), SPC and CAPSLE program. The TAU group was the control. The SPC arm included child psychiatric residents assessing high risk students due to their aggressive behavior, internalizing or poor academic performance. The residents would assess and refer children to appropriate treatment. The CAPSLE program involved a manualized program based in psychodynamics that addressed bullies, victims and bystanders. This program included teacher education, students receiving self-defense classes and continued consultations with

counselors and teachers. Part of the CAPSLE program included positive reinforces for the children, notifications to parents for poor behavior, and anti-bullying videos. Results showed that the CAPSLE program significantly reduced aggression, off-task, and disruptive behaviors, aggressive bystanding and overall victimization compared to TAU and SPC.

Kiusaamista Vastaa (KiVa) (Salmivalli & Poskiparta, 2012)

The term *Kiusaamista Vastaa* means “against bullying” and KiVa means “nice”. The extensive program is now present in about 82% of Finnish schools and includes teacher training, student peer groups, communication with parents and an anti-bullying computer game. The game includes lessons and virtual bullying incidents. Teacher training included lessons, improved visibility during recess and lunchtime. Lastly, the student peer groups included peer positive role models and utilized both punitive and non-blame approaches. After nine months of implementation, data showed that bullying and victimization was significantly decreased in grades 1 to 6, but results were mixed in grades 7 to 9. The results also showed that KiVa increased students’ school liking, academic motivation and academic performance when compared to control schools.

The Bernese Program (Be-Prox) (Alsaker & Valkanover, 2012)

In Switzerland, Be-Prox was initiated in preschools to take advantage of the benefits in a preschool classroom, including a student’s respect for their teachers, higher teacher to child ratio and greater flexibility to teaching. The program involved extensive lessons and consultations for teachers to improve their response to bullying situations in six modules designed to take place over four months. Results showed that teacher’s confidence improved and reduced victimization in the young students.

Transtheoretical-based Tailored Anti-bullying Program (Evers, Paiva, Johnson, Cummins, Prochaska, & Gokbayrak, 2012)

This program studied middle and high school students and included three 30 minute multimedia videos to be completed at the student’s leisure as well as a 10-page supplementary guide for teachers and parents with optional additional activities. Analysis showed a decrease in victimization in this age group.

South Carolina Program (Melton, Limber, Flerx, Nation, Osgood, Chombers, & Olweus, 1998)

This intervention included targeting needs at many levels of a student’s life, including the classroom, individual and community levels. Prior to implementation, multiple meetings were done to target “hot spots” of bullying and determine each school’s needs. The results were

presented to schools in order to improve awareness in students. In classrooms, teachers adhered to strict behavioral rules, including positive reinforcement of pro-social behavior and punishment of bullying behaviors. There were also videos, computer games, and newsletters at teacher's disposal. Prominent members of the community were also engaged to improve the overall culture regarding bullying. This included anti-bullying programs in church and during extracurricular activities. Also, parents of bullies were required to meet with school officials and safety plans were made for chronic victims. Lastly, mental health professionals were involved when deemed necessary in chronic bullies and victims.

Bully-Proofing Your School (BPYS) (Menard, Grottpeter, Gianola, & O'Neal, 2007)

Another comprehensive program is BPYS that focused on elementary and middle school students. Components of BPYS included evaluating the extent of bullying in each individual school with questionnaires, teaching students assertiveness skills to protect themselves from bullying and creating a more positive school environment to decrease students being negative peer bystanders. Over three years BPYS implemented once weekly classroom meetings, seven sessions of classroom interventions and individual consultation with parents of children who were chronic bullies or victims. Results showed more strongly in elementary schools compared to middle schools. However, the program showed decreased bullying behavior and school violence, as well as improved attitudes in students regarding bullying.

Toronto Anti-bullying Program (Pepler, Craig, Ziegler, & Charach, 1994)

The aim of this program was preventing bullying at several levels, including individual, classroom and with parents. Three critical elements included staff training, firm limit setting and improved playground supervision. Information about this program was sent home, and parents were invited to participate in information nights. Individual intervention took place between specific bullies and victims, with close follow up.

Norwegian Anti-Bullying Program (Galloway & Roland, 2004)

The main principle of this program revolves around investing in teachers' abilities to improve students' quality of life and coping skills. Teacher training was intense and included nine months of four days per week trainings with handouts as well as two-hour peer supervisions.

SAVE (Ortega, Del Ray, & Mora-Merchan, 2004)

In Spain, this program looked to improve cooperation, problem solving, and a desire for mutual understanding by peer conflict resolution. Specifically, the program gave students the

opportunity to participate in decision making and proposing solutions. Some options included quality circles, peer support, assertiveness, and empathy training. Teachers and families were encouraged to participate in training sessions, however the extent this occurred varied among schools.

Kia Kaha (Raskauskas, 2007)

In the Maori language in New Zealand, the words Kia Kaha means “be strong”. This holistic program looks to incorporate social sciences and health/physical well-being. The program was initially implemented by Police Education Officers (PEOs) who are trained educators who work with youths. The PEOs went to schools and encouraged principles to adopt this program. If accepted, the PEOs trained teachers, hosted parents’ night and taught several areas of the curriculum.

Respect Program (Ertesvag & Vaaland, 2007)

The four principles behind the Respect program in Norway were common sense-based and important to all anti-bullying programs. First, adults are authority figures and should act as such. Next, all individuals in a school should be involved in the program. Also, adults should act consistently to impact student behavior. Lastly, there should be a long-term commitment that is continuous for all students. Based on these principles, there were multiple training sessions for all adults involved in school education and planning. Designed as a cohort longitudinal study, the effects were moderate and showed some improvement in problem behavior, which varied among grade levels.

Finnish Anti-Bullying Program (Salmivalli, Kaukiainen, & Voeten, 2005)

The basis of this program is teacher education to raise awareness of bullying, encourage student’s self-reflection on their own behavior, and improve an overall commitment to anti-bullying behaviors. Over a one year period of training, teachers were given active feedback on situations from their classrooms, and were given educational materials to use in classroom teachings. Schools that adhered closely to the regimen had stronger effects, but overall improvements were noted in decreased frequency of observed and experienced bullying, improved attitudes and beliefs.

There are overlaps and similarities in many of these programs. The meta-analysis looked at the most important elements present in a program that would lead to greater successes. (Farrington et al., 2009) These elements include parent/teacher meetings, disciplinary methods, the duration and intensity of the program for both children and teachers. The more elements a program had, the higher likelihood the program will decrease victimization and bullying.

Unexpectedly, some programs appear to worsen bullying behaviors and victimization. (Farrington et al., 2009) The Expect Respect Program, developed initially for students who have experienced sexual harassment or dating violence, was found to have a detrimental effect on victimization, which was attributed to intense work with peers. (Meraviglia, Becker,

Rosenbluth, Sanchez, & Robertson, 2003) This program consists of support groups for middle school and high school aged girls. Although the meta-analysis does not provide a hypothesis for why this program worsened bullying behavior, there has been increasing concern that peer conflict resolution and mediation does not improve the situation, and may worsen the harassment. One of the definitive aspects of bullying is a power imbalance between bully and victim. In a private mediation or peer support model, the power the bully has over their victim may be abused and the victim may not be fully able to participate or discuss the problems. (Theberge & Karan, 2004) Elizabeth Englander uses the analogy of spousal abuse, where we cannot expect a victim to be completely honest with their abuser sitting in the same room as them. (Englander, 2012) Also, the bullies, especially those with stable aggressive tendencies, do not take mediation seriously, and can attempt to charm the mediators or lie to them in order to avoid punishment. (Englander, 2004)

One limitation to implementing beneficial programs on a larger scale is the lack of federal laws and policies. Each state is left to itself to define and address bullying. Most states include both laws and policies discussing bullying and peer harassment, however the state of Montana only has policies on the issue. Arizona, Illinois, Indiana, Kansas Minnesota, North Dakota, and Texas only have laws on the issue, not policies. Further information can be found at www.stopbullying.gov.

Beyond school involvement, individual-level interventions may be appropriate when internalizing and externalizing symptoms or other signs of physical or psychological distress are present. Whether the client is a bully, a victim, or a bully-victim, if s/he presents with signs and symptoms of distress, it is important to seek care from a trained mental health professional or health care provider for therapy and/or medication management. Internalizing symptoms typically include depression and anxiety. Symptoms of depression include sleep and appetite changes, anhedonia (loss of interest in previously pleasurable activities), poor energy and concentration and suicidal ideation. Symptoms of anxiety include perseverative worry leading to poor concentration or sleep, panic attacks, and obsessions/compulsions. Externalizing symptoms can include anger, aggression, stealing, harming animals, setting fires for pleasure and threatening to kill others. If any of the above symptoms are present, it is important to seek individual mental health treatment for the child, whether they are a bully/victim or combination.

One last area to focus on is cyberbullying, which is defined as “an aggressive, intentional act carried out by a group or individual, using electronic forms of contact, repeatedly and over time against a target who cannot easily defend him or herself.” (Smith, Mahdavi, Carvalho, Fisher, Russell, & Tippett, 2008) Cyberbullying includes receiving threatening messages, spreading rumors, having private emails sent to others, or having an embarrassing picture posted without consent. (Englander, 2012) The increase in cyberbullying experiences are attributed to increased use of the Internet among children and adolescents. In a recent study, 39% of children in grade 5 and 83% in middle school report using computers and mobile devices regularly. (Englander, 2012) In a study of Internet users 12 to 17 years old, approximately one third of Internet users report being targeted for cyberbullying and 20% admitted to being a cyberbully themselves. (Pew Internet and American Life Project, 2007) However other studies assess the prevalence of cyberbullying closer to 10%. (Vandebosch & Van Cleemput, 2009) The prevalence of cyberbullying may depend on the way the children were asked, with lower percentages responding yes to direct questions of cyberbullying and higher percentages endorsing specific harmful Internet behaviors (i.e., sending anonymous

emails, posting a picture without permission, hacking into someone's webpage). (Hinduja et al., 2010)

When cyberbullying is identified in a community, there are multiple areas of intervention. These include informing all relevant adults, informing and educating cyberbullies about the consequences of their behavior, and ensuring that a victim has a safe adult they trust with whom to speak. (Englander, 2012) Most often, the adults utilized in this plan are parents or guardians at home and the school is less often involved. Therefore, education and interventions must be taught to this group of adults, as the programs discussed above will not reach the adults at home. Close adult monitoring of the child or teen's usage of the Internet is cited as an important behavior for parents and guardians. (Englander & Schank, 2010)

Overall, there are multiple strategies to address bullying. The most extensive area of research is focused on prevention of bullying in school, but there is growing interest in bullying out of school and cyberbullying. The most successful programs include communication between students, teachers, and parents, are of higher intensity and length, and utilize strict behavioral modification, with rewards and punishment. Each program can be tailored to a specific school or community's needs. With the increased risk of multiple psychiatric complications, one other aspect that must be considered is the possibility of referral for psychiatric assessment. Kumpulainen et al. (1998) found that while more children involved in bullying were referred for assessment when compared to those not involved, "only a minority of disturbed children were actually referred." There is hope for a child that is being bullied or victimized, but it will take changes at many levels of that child's life.

CONCLUSION

Childhood involvement in bullying as victim, bully, or bully-victim is prevalent and associated with increased risks for internalizing problems, suicidal ideation, externalizing problems, somatic concerns, academic difficulties and social consequences. Although evidence is emerging to identify factors that put a child at increased risk of becoming involved in bullying, more research is still needed for reliable identification. While reliable identification of children at risk of being bullied or becoming bullies will help improve preventive measures, it would also help target those that would benefit from early psychiatric referral and interventions. Robust evaluation of prevention and intervention programs should continue. Intervention strategies vary and have been utilized for several decades. As described by one of the leading bullying researchers, Dr. Dan Olweus, treatment for bullying must be comprehensive and address individual, school and community-wide problems, and the most successful programs utilize these principles. It is important to continue to reassess the avenues for new forms of bullying such as bullying that occurs online, as this is a growing area of concern for today's generation.

¹Clarkson University, Potsdam, NY, United States

²Nipissing University, North Bay, ON, Canada

ABSTRACT

There is a plethora of research demonstrating that youth who are involved in bullying as victims, bullies, and bully-victims experience mental and physical health problems (e.g., Crick et al., 1999; Miller & Vaillancourt, 2007; Owens, Slee, & Shute, 2000; Swearer, Espelage, Vaillancourt, & Hymel, 2010). We will begin this chapter by reviewing literature demonstrating the link between bullying and physical and mental health problems. First, we review literature showing that the negative health outcomes associated with bullying exist both concurrently and longitudinally. Second, we examine predictors of bullying involvement as well as risk factors for developing health problems due to bullying (e.g., personality, previous bullying involvement). In addition, we will consider variables that moderate the link between bullying involvement and having health problems (e.g., social support, genetics). Third, we consider the various effective and ineffective coping strategies used by school-aged children to deal with both bullying and health problems (e.g., aggressive behaviors, defense mechanisms). Fourth, we examine whether the predictive factors and coping strategies associated with bullying and health problems differ at various stages of school (i.e., preschool, elementary, middle, high school). Finally, we consider the health outcomes in children who are considered bullies, bully-victims, and bystanders, and discuss the implications of our review and suggest avenues for future research. Given the complex interactions between bullying involvement and mental and physical health problems, we demonstrate the need for a multidimensional approach to bullying intervention and children's health promotion.

INTRODUCTION

Bullying occurs when a person intentionally uses repeated aggression to target a peer who has less power (Olweus, 1993). The intentional use of repeated aggression can take different forms including physical, verbal, relational/social, or cyber bullying and can be either direct/overt (e.g., physical attacks) or indirect/covert (e.g., spreading rumors) in nature. Both bullying and being bullied (i.e., peer victimization) have been robustly linked with poor mental and physical health outcomes (e.g., Crick et al., 1999; Miller & Vaillancourt, 2007; Swearer, Espelage, Vaillancourt, & Hymel, 2010). The negative mental and physical health outcomes associated with bullying involvement are concerning given that an estimated 10% of school-age children are frequently bullied and approximately 30% of children are occasionally bullied (e.g., Limber & Small, 2003). Fekkes, Pijpers, and Verloove-Vanhorick (2005) reported that 5.5% of school-age children regularly bullied others and approximately 32% of children occasionally bullied others. Wolke et al. (2000) examined involvement in direct and relational bullying among 6 – 9 year old children; they found that of the students involved in bullying, 39.8% and 37.9% were victims, 4.3% and 1.1% were bullies, and 1.4% and 5.9% were bully-victims (i.e., both bullies and victims) of direct and relational bullying, respectively.

In this chapter, we start by reviewing literature demonstrating a link between school-aged children involved in bullying (i.e., bullies, victims, bully-victims, bystanders) and health problems. We then examine predictors of who is involved in bullying and at risk for developing health problems. Next, we consider coping strategies to deal with bullying and health problems. We focus our chapter on bullying/peer victimization occurring among school-age children. Where possible, we also examine the various bullying roles (i.e., bully, victim, bully-victim, bystander).

BULLYING AND HEALTH PROBLEMS

Mental Health Problems

The relationship between mental health problems and bullying involvement is well established (e.g., Rigby, 2000; Swearer, Espelage, Vaillancourt, & Hymel, 2010). Kochenderfer-Ladd and Wardrop (2001) examined loneliness and social satisfaction as a function of victimization status in children from kindergarten to 3rd grade. They found that children who moved from non-victim to victim status showed increasing levels of loneliness and decreasing social satisfaction. However, children who moved from victim to non-victim status did not necessarily have improvements in loneliness or social satisfaction. Moreover, Hawker and Boulton (2000) reported meta-analytic findings suggesting that peer victimization was strongly related with depression. In Finnish 8th and 9th graders, Kaltiala-Heino, Rimpelä, Rantanen, and Rimpelä (2000) found that bully-victims were most likely to have symptoms of depression and anxiety when compared with bullies and victims. Given that school-age children who experience peer victimization have higher levels of depression and anxiety than non-victimized children, it is not surprising that children and adolescents who are victimized are also more likely to have suicidal thoughts and suicidal attempts than non-victims (Heilbron & Prinstein, 2010). Moreover, Bonanno and Hymel (2010) found that the association between

peer victimization and suicide ideation in adolescents in 8th to 10th grade was partially mediated by feelings of social hopelessness. However, Bonanno and Hymel did not find mediation effects for feelings of general hopelessness. Their results suggest the importance of positive peer relationships for mental health.

It is important to note that the relationship between mental health problems and bullying involvement is bidirectional. For example, Egan and Perry (1998) found that among children in 3rd to 7th grade low self-regard (assessed as self-perceived social competence and assertiveness) in the fall predicted more peer victimization over the school year (controlling for fall victimization, sex, age, and behavioral risk factors); likewise, peer victimization in the fall predicted reduced self-regard (i.e., perceived social competence) in the spring.

Involvement in bullying has been linked to a number of mental health problems beyond internalizing difficulties. Arseneault et al. (2006) found that children who were peer victimized had more internalizing problems than control children; girls who were victimized also had more externalizing problems than control girls (a significant effect for externalizing problems was not found for boys). Interestingly, children who were identified as bully-victims had more internalizing and externalizing problems than both victimized and control children. Both victims and bully-victims had more behavioral and school adjustment problems than control children. Second grade children classified as bullies and bully-victims were also more likely to have attention deficit disorder and oppositional/conduct disorder than victims and control children (Kumpulainen, Räsänen, & Puura, 2001). Furthermore, there is evidence that peer victimization is associated with psychotic symptoms. Arseneault et al. (2011) found that 12 year olds who were either peer victimized or maltreated by adults had higher reports of delusions and hallucinations than children who did not experience victimization by peers or adults. Schreier et al. (2009) also found that 12-year-old children who were peer victimized were twice as likely to have psychotic symptoms than children who were not victimized. The above findings collectively demonstrate the negative mental health effects for school-age children involved in bullying/peer victimization.

Physical Health Problems

There is a robust relationship between reports of peer victimization and poor physical health; people who report experiencing peer victimization also report more physical health problems than people who do not report peer victimization (e.g., Greco et al., 2007; Rigby, 2003). Longitudinal evidence suggests that peer victimization predicts health problems rather than health problems predicting peer victimization. Children between 9 – 11 years of age who were peer victimized at time one were more likely to have developed new somatic problems (e.g., headaches, bedwetting, stomach pain) and psychosocial problems (e.g., depression, anxiety) six months later compared to non-victimized children (Fekkes et al., 2006). Somatic problems at time one did not predict peer victimization at time two; in contrast, having symptoms of either depression or anxiety at time one did predict time two peer victimization. Knack, Iyer, and Jensen-Campbell (2012) found a similar pattern with college-age students in which peer victimization in the fall semester predicted physical health in the spring semester even after controlling for initial health differences. Biebl et al. (2011) also conducted a longitudinal study assessing the relationship between chronicity of peer victimization and

health in which participants were assessed at age 5, between ages 10 – 18, and again between ages 12 – 20. They found that chronic victims (i.e., victimization at all three assessments) had more physical health problems than non-victims; no physical health differences were found between chronic victims and desisters (i.e., victimization at an early time point but not at time three). Biebl and colleagues also examined the specific types of health problems experienced and found that chronic victims experienced more headaches than both non-victims and desisters; late-onset victims (i.e., victimization at a later time point but not at time one) experienced more headaches than non-victims.

Wolke, Woods, Bloomfield, and Karstadt (2001) examined whether physical health symptoms (e.g., headache, stomach aches, sore throat, skin problems) and psychosomatic health problems (e.g., bed wetting, sleep problems, worried about school) differed for 6 – 9 year old children who were classified as either a bully, bully-victim, or victim. They found that for direct bullying, victimized children had more physical and psychosomatic health problems than non-victims; victimized children did not differ from bully-victims. No differences in health were found for relational bullying. Less empirical research has examined the physical health status of children identified as bullies or bully-victims.

The above research collectively demonstrates that being involved in bullying/peer victimization is associated with both mental and physical health problems. Given the increased likelihood of experiencing mental and physical health problems, researchers have examined factors that predict who is likely to be involved in bullying/peer victimization as well as factors that protect children from the negative health effects associated with bullying. In the next section we review the different risk and protective factors.

RISK AND PROTECTIVE FACTORS

Previous Bullying Involvement

Early involvement in bullying predicts later involvement in bullying (Arseneault, Bowes, & Shakoor, 2010). Even in early elementary school, children's involvement in bullying is fairly stable. Children who were bully-victims in 1st grade were still bully-victims in 3rd and 5th grade (Burk et al., 2011). Children who were bully-victims in 1st grade who did not remain bully-victims were likely to be classified as bullies or victims rather than as socially adjusted (i.e., low bullying and low peer victimization). Burk et al. also found that bullies in 1st grade were likely to either remain bullies or move to the socially adjusted group. Scholte et al. (2007) found that 43% of children who were peer victimized and 46% of children who bullied others at 11 years of age were still experiencing peer victimization and engaged in bullying, respectively, four years later.

Early involvement in bullying also predicts later health outcomes. For example, long-term victimization is associated with mental health problems. Italian students ranging from 13 to 20 years of age ($M = 15.12$ years) who retrospectively reported stable peer victimization (both as a victim and as a bully-victim) reported more internalizing problems than students who experienced a later-onset of peer victimization; no significant differences were found for externalizing problems (Menesini, Modena, & Tani, 2009). Students who experienced stable peer victimization were more anxious and depressed than their peers who experienced later

onset of victimization; stable compared to late-onset bully-victims reported more symptoms of withdrawal. These results suggest students with stable long-term experiences of peer victimization during school are at higher risk for mental health problems than students who are short-term targets of peer victimization.

Personality and Individual Differences

Several personality and individual difference variables are associated with bullying involvement and health. We do not intend our review of personality and individual differences to be exhaustive. Instead, we present several examples of personality and individual differences that may be influential in advancing our understanding the relationship between bullying involvement and health. Although Knack, Iyer, and Jensen-Campbell (2012) found that self-reported peer victimization predicted physical health even after controlling for individual differences related to both social relationships and health, we nevertheless believe it is important to consider individual differences in bullying involvement and in susceptibility to poor health and poor health behaviors. This consideration of individual differences and personality may provide a more nuanced understanding of the association between bullying involvement and health.

One individual difference is the need to belong. Although researchers have noted that humans have a fundamental need to belong to social groups and to have interpersonal relationships that are significant and long-lasting (Baumeister & Leary, 1995), individuals vary on the intensity of their need to belong. Levels of the need to belong influence the amount of socially-relevant information remembered during social interactions (Gardner, Pickett, & Brewer, 2000). For examples, Gardner and colleagues found that rejected individuals (whose need to belong was experimentally threatened) recalled more socially-relevant information than accepted individuals. Pickett, Gardner, and Knowles (2004) found that college-age students with a high need to belong were more attentive to and accurate in decoding verbal and non-verbal social cues (i.e., vocal tone, facial emotion, empathic accuracy) than students with a low need to belong. It is likely that being more attentive and accurate in decoding social cues allows students to more effectively navigate social groups. There is also a relationship between belongingness and physical health. For example, Begen and Turner-Cobb (2011) found that early adolescents between 11 – 14 years of age who self-reported high levels of feeling like they belonged also reported fewer physical health symptoms.

Rejection sensitivity is characterized by a tendency to anxiously expect, readily perceive, and overreact to rejection (Downey & Feldman, 1996). In ambiguous situations, individuals who are high on rejection sensitivity are more likely to perceive that they have been intentionally rejected than individuals who are low on rejection sensitivity. Downey and Feldman also demonstrated that individuals high on rejection sensitivity are less satisfied with their interpersonal relationships than those who are low on rejection sensitivity. Rejection sensitivity has been theorized to be a personality dimension that can be learned after repeated social rejection or inability to satisfy the need to belong to a social group (Levy et al., 2001). Rejection sensitivity predicts mental health problems such as loneliness, social withdrawal, social anxiety, and distress (Downey, Lebolt, Rincón, & Freitas, 1998; London, Downey, Bonica, & Paltin, 2007; Watson & Nesdale, 2012). Downey, Lebolt, Rincón, and Freitas found that children high on rejection sensitivity were more distressed following an ambiguous

rejection experience than children low on rejection sensitivity. Children high on rejection sensitivity also had more difficulties with peers and teachers and were more likely to engage in disruptive/oppositional behavior than children low on rejection sensitivity. In college-age students, Watson and Nesdale found that the relationship between rejection sensitivity and loneliness was mediated by social withdrawal as a way to cope with possible rejection.

A plethora of research has shown that the Big Five personality characteristics (i.e., agreeableness, extroversion, conscientiousness, neuroticism, openness to experience) are associated with social relationships. Among 5th to 8th grade students (Jensen-Campbell & Malcolm, 2007) and 10 to 13 year old children (Bollmer, Harris, & Milich, 2006) high peer victimization was correlated with low conscientiousness. Jensen-Campbell et al. (2002) found that peer victimization was also correlated with low agreeableness in middle school children. Bollmer, Harris, and Milich also found that bullying was correlated with lower levels of conscientiousness and lower levels of agreeableness. Tani, Greenman, Schneider, and Fregoso (2003) examined Big Five personality characteristics in 8 to 10 year old Italian children in respect to their bully involvement. They found that children who were victims scored lower than outsiders and children who defended the victim on agreeableness and conscientiousness but higher on emotional instability. Children who were bullies (either the actual bully or supported the bully) were lower on agreeableness than children who defended the victim; bullies were also higher on extroversion than outsiders. Defenders scored highest on agreeableness but were lower on emotional instability than both bullies and victims. Perhaps more importantly, researchers are examining why these relationships exist. For example, Bollmer et al. (2006) found that the association between conscientiousness and peer victimization was mediated by negative affect; low conscientiousness predicted more negative affect (higher anger, distress, and blame; lower forgiveness) which in turn predicted peer victimization. They also found that more agreeable children felt more guilt when bullying others and in turn were less likely to bully other children; low conscientious children had higher skin conductance levels while describing a time they bullied others which in turn predicted higher levels of bullying. Jensen-Campbell and colleagues (2002) found that agreeableness moderated the relationship between behavioral vulnerabilities and peer victimization suggesting that being agreeable may help buffer children with behavioral vulnerabilities from being victimized by their peers. Some research suggests that extroversion and neuroticism are associated with bullying involvement (e.g., Connolly & O'Moore, 2003); however, these associations are less established.

Although researchers have also found robust associations between the Big Five personality characteristics and health, these relationships are typically examined in college students (e.g., Raynor & Levine, 2009) and adults (e.g., Chapman et al., 2006; Goodwin & Engstrom, 2002). The adult research primarily links Big Five personality characteristics with health behaviors such as smoking, healthy eating, exercise, adherence to medical treatment plans, and visits to the doctor. Similar associations between Big Five personality characteristics and health behaviors have been found for school-age children. For example, de Bruijn et al. (2005) found that agreeableness and openness to experience was correlated with vegetable consumption in adolescents 12 to 18 years of age; in addition, openness to experience was correlated with fruit consumption. They also found that extroversion was correlated with physical activity related to sports. Moreover, Big Five personality characteristics in childhood, especially agreeableness and conscientiousness, predict health in adulthood (e.g., Friedman et al., 1993; Hampson et al., 2007). Given the empirical evidence linking Big Five personality characteristics with both

bullying involvement and with health and health behaviors, we encourage researchers to continue to consider whether these characteristics influence the association between bullying involvement and health.

Social Support

Children's social support systems also modulate involvement in bullying as well as mental and physical health outcomes associated with peer victimization. Social support refers to the degree to which one (actually or perceivably) receives care, assistance, or support from other individuals such as parents/caregivers, teachers, or peers (Knack, Waldrup, & Jensen-Campbell, 2007). Social support is a broad, multifaceted construct which consists of emotional support (i.e., someone to listen sympathetically, to show care or empathy), instrumental support (i.e., providing practical help), informational support (i.e., provision of knowledge relevant to solving problems), companionship support (i.e., participating in leisure activities), and validation (i.e., providing information about normative or appropriate social behavior) (see Wills, 1985; Wills & Shinar, 2000 for review).

Social support relates to both the perpetration and victimization of bullying behaviors among youth. In a large nationally representative sample of 6th to 10th graders, Wang, Iannotti, and Nansel (2009) examined the relationships between social support and frequency of bullying and peer victimization. Results showed that students who received more parental support were less likely to be involved in aggressive behavior as bullies, victims, or bully-victims. Stadler et al. (2010) found that parental support buffered the relationship between peer victimization and maladjustment, especially for girls.

Beyond parental support, peer support helps to create a positive and caring social climate for youth (Naylor & Cowie, 1999). Wang et al. (2009) showed that peer support (assessed as number of friends) was associated with less physical, verbal, and relational (but not cyber) victimization. The insignificant relationship between number of friends and cyber victimization may be rooted in the anonymity and ease of cyber-bullying, wherewith perpetrators become disinhibited as they can harm the victim anonymously without fear of reprisal from the victims' social group (e.g., Li, 2006). Interestingly, students' number of friends was related to perpetrating more physical, relational, and verbal bullying behavior (Wang et al., 2009). Researchers have long suggested that peer aggression may be a tactic for achieving power, affiliation, and status from the peer group (e.g., Arnocky & Vaillancourt, 2012; Espelage & Holt, 2001). Although peer support may help to curtail victimization, it might also empower or motivate some youth to engage in aggressive behavior (see also Salmivalli, Huttunen, & Lagerspetz, 1997).

Receiving social support also relates to more effective coping and higher levels of well-being (e.g., Cowie, 2000; Cowie & Hutson, 2005). Cohen and Wills (1985) suggested that meaningful social support helps to ease or buffer distress and social pain (e.g., Finch, Okun, Pool, & Ruehlman, 1999) as well as physical pain (e.g., Lidderdale & Walsh, 1998; Phillips & Gatchel, 2000; Chalmers, Wolman, Nikodem, Gulmezoglu, & Hofmeyer, 1995). Researchers have since noted that perceived support (versus actual or received support) is particularly important to buffering the stress-health relationship (Wills & Shinar, 2000). For instance, Rigby (2000) found that both peer victimization status and level of perceived social support (from teachers, peers, and parents) independently predicted unfavorable scores on the General Health

Questionnaire (Goldberg & Williams, 1991) which is a measure of somatic, anxious, social dysfunction, and depressive symptoms. Holt and Espelage (2007) found that youth involved in bullying either as victims, bullies, or bully-victims who had moderate social support also experienced less depression and anxiety compared to less supported children. The combination of being a bully-victim and having low perceived social support also related to more suicidal ideation (Rigby & Slee, 1999).

Given the importance of social support to issues of bullying and health, it is particularly disconcerting that boys are less likely to act as peer supporters (e.g., Cowie, 2000) and tend to receive less prosocial behavior from peers compared to girls (Crick & Grotpeter, 1996). Even if boys have a sufficient social support system in place, they may be less motivated than girls to utilize it. Furthermore, boys often refrain from reporting peer victimization (Cowie, 2000). As social support is provided in times of need, a boy whose victimization goes unidentified will be unlikely to receive the necessary support, even if it is available.

Of further concern is the relationship between peer victimization, peer support, and psychological health outcomes among youth who are in the sexual minority (gay, lesbian, bisexual, and questioning). Williams, Connolly, Pepler, and Craig (2005) found that both peer victimization and peer support mediated the relationship between sexual orientation and psychological symptoms, where victims had more depression and externalizing symptoms and socially supported youth had less depression and externalizing symptoms. Unfortunately, Williams et al. also found that, on the whole, sexual minority youth are also less likely to receive peer support than were sexual majority youth.

Family-level Factors

Family-level variables are also associated with bullying involvement. Among preschool children from predominantly low-income families, maternal empathy, age-appropriate expectations, and power over children were correlated with preschool children's level of bullying such that low empathy, inappropriate age expectations, and valuing power (over children's independence) predicted higher levels of overt and relational bullying (Curtner-Smith et al., 2006). Similarly, kindergarten children with parents high on intrusive demandingness (i.e., providing children with little control on social decisions) were more likely to experience peer victimization than kindergarten children with parents low on intrusive demandingness; children with responsive parents were less likely to be peer victimized than children with less responsive parents (Ladd & Ladd, 1998). Barker et al. (2008) examined the relationship between trajectories of peer victimization in elementary school children and family-level variables. Children in the high/chronic peer victimization trajectory group were more likely to have experienced harsh reactive parenting, insufficient family income, and be more physically aggressive than children in the low/increasing peer victimization trajectory group. Children with a moderate/increasing peer victimization trajectory were more likely to be physically aggressive and come from a family with insufficient family income than children with a low/increasing trajectory of peer victimization. The only variable Barker et al. found to distinguish children with a high/chronic trajectory of peer victimization from those with a moderate/increasing trajectory was harsh reactive parenting. Similarly, Bowes et al. (2010) found that a positive home environment (e.g., maternal and sibling warmth, positive atmosphere) buffered children who experienced peer victimization from emotional and

behavioral adjustment problems. Collectively the above research suggests that poor parenting is associated with increased likelihood of bullying involvement among school children.

However, Harris (2000) cautioned against drawing causal conclusions from correlational data. Harris (1995, 2000) argued that parents' influence on children's behavior outside of the home was minimal and indirect (e.g., parents influence children's peer relationship through the neighborhood children are raised in) rather than direct; she postulated that peer groups were stronger socialization agents than parents. Fitting this postulation, researchers have suggested that bullying involvement predicts parenting practices (rather than vice versa). Kokkinos and Panayiotou (2007) found that parenting styles did not predict elementary school children's bullying involvement; rather, children's bullying involvement significantly predicted parenting practices such as rule setting. It is feasible that parenting practices are elicited as a response to children's bullying involvement (e.g., evocative parenting; Scarr & McCartney, 1983). For example, Narusyte et al. (2011) found that mothers' harsh criticism was evoked by adolescents' externalizing problems (but fathers' criticism predicted adolescents' externalizing behaviors).

Physiological Factors

It is also important to consider physiological processes when examining the relationship between bullying involvement and health. Although little work has examined the brain activity in people involved in bullying (see Knack, Gomez, & Jensen-Campbell, 2009), researchers have examined how people respond to social exclusion. Eisenberger, Lieberman, and Williams (2003) found that the dorsal anterior cingulate cortex (dACC) was more active when college students were socially excluded from a ball tossing game than when they were socially included. The dACC was also positively correlated with self-reported distress; that is, higher levels of self-reported distress were associated with more activity in the dACC. Eisenberger, Lieberman, and Williams also found that the right ventral prefrontal cortex was more active during social exclusion than social inclusion and was negatively correlated with self-reported distress; higher levels of self-reported distress were associated with less activity in the right ventral prefrontal cortex.

Similar results were found among adolescents who played a ball-tossing game (Masten et al., 2009, 2011); adolescents' right ventrolateral prefrontal cortex was more active during social exclusion than during social inclusion and was associated with higher self-reported distress levels. There was also more activation in the ventral striatum when adolescents were socially excluded compared to when they were included. Masten and colleagues (2009) theorized that the activation in the ventral striatum seen among adolescents may be indicative of attempts to engage in affective regulation. Masten et al. (2011) conducted a longitudinal study with adolescents examining whether neural activation during social exclusion predicted depressive symptoms one year later. They found that although subgenual anterior cingulate cortex (subACC) activity during exclusion was not associated with concurrent symptoms of depression, higher levels of subACC activity predicted depressive symptoms one year later. Activity in the frontal cortex, cingulate cortex, and precuneus was also associated with current and subsequent symptoms of depression. Masten and colleagues suggested that higher subACC activity during social exclusion may be an indication of sensitivity to rejection and who is at higher risk of subsequently showing symptoms of depression. Sebastian et al. (2010) conducted a study comparing how young adolescents ($M_{age} = 12.8$ years), middle adolescents ($M_{age} = 15.0$

years), and adults ($M_{\text{age}} = 27.4$ years) responded to social exclusion compared to social inclusion. Although they did not find significant differences in threats to psychological needs, they did find that both young and middle adolescents had lower overall moods following social exclusion compared to social inclusion and that young adolescents felt more anxious when socially excluded compared to being included. No significant differences for mood or state anxiety were found among adults. These results suggest that although adolescents and adults feel similarly threatened by social exclusion, early adolescents respond more emotionally than adults do to social exclusion.

There is also evidence linking brain activity with individual differences and interpersonal relationships. Masten and colleagues (2009) found that adolescents high on rejection sensitivity had more activity in the dACC, precuneus, and anterolateral prefrontal cortex during social exclusion than adolescents low on rejection sensitivity. Burkland, Eisenberger, and Lieberman (2007) also found that college students who were high on rejection sensitivity had more dACC activity than those low on rejection sensitivity when viewing disapproving faces (no differences were found when viewing faces depicting anger or disgust). Kross et al. (2007) showed college students pictures that had either a rejection or acceptance theme as well as control pictures. They found that all participants showed activation in neural regions associated with processing affective stimuli and cognitive control. However, participants who were low on rejection sensitivity had more activity in regions of the frontal cortex while viewing rejection compared to acceptance themed pictures than participants high on rejection sensitivity; this frontal cortex activity was associated with lower self-reported distress. These findings suggest that people respond differently to rejection (e.g., social exclusion, disapproving faces, rejection-themed pictures) depending on their level of rejection sensitivity. Although much of this research has been conducted with college-age students, the results suggest the importance of considering neural responses among students involved in bullying and whether differences in neural activation are associated with bullying status and health outcomes.

Bullying involvement is also associated with differences in hormone levels. For example, children who experience peer victimization have lower morning cortisol levels than those who are not peer victimized (Hansen et al., 2006; Kliewer, 2006; Knack, Jensen-Campbell, & Baum, 2011; Vaillancourt et al., 2008). Moreover, Knack, Jensen-Campbell, and Baum (2011) found that lower morning cortisol levels mediated the relationship between peer victimization and health problems; adolescents who experienced peer victimization had a flatter cortisol awakening response which in turn predicted more health problems.

During an acute social stressor in which children (Ouellet-Morin et al., 2011) and adolescents (Knack, Jensen-Campbell, & Baum, 2011) prepared and delivered a speech, youth who were victimized by their peers had *lower* cortisol levels after the social stressor compared to non-victimized youth. This finding is interesting given that Blackhart, Eckel, and Tice (2007) and Stroud, Salovey, and Epel (2002) found that participants who were rejected had *higher* cortisol levels than non-rejected participants. The difference between cortisol levels following an acute social stressor could be due to the use of different social stress tasks (speech delivery versus rejection/acceptance manipulation) or to the consideration of individual differences in participants' daily experiences with peer victimization. Moreover, Knack and colleagues found a mediation effect such that peer victimization predicted lower cortisol levels 30 minutes after adolescents delivered their speech which in turn predicted more visits to the doctor/nurse. This finding is not surprising considering Slavich et al. (2010) found that the social evaluative stress of delivering a speech led to increased inflammatory activity in college students. Interestingly,

the inflammatory reaction was associated with neural activity in the dACC and insula. Future research should continue examining how the body responds to the social stress of bullying involvement and whether the physiological response is associated with health outcomes.

Genetics

Researchers have begun to explore the biological factors which may influence aggressive behavior among youth. At present, specific genetic factors affecting aggressive behavior among youth are poorly understood. However, a body of evidence from a variety of animal species suggests that aggression is, to a degree, heritable. This heritability is most readily observable in the selective breeding within some animal species for the purposes of enhancing aggression (e.g., Nelson, 2006). Among humans, adoption studies have shown concordance between both parents and their children (Cadoret & Stewart, 1991) as well as among twins (e.g., dizygotic v. monozygotic) on aggressive personality characteristics (see Rhee & Waldman, 2002). However, some studies have simultaneously highlighted the confounding factors of measurement methodology (i.e., observational versus self- or parent-reports) and familial environment influences which also influence family concordance rates (Miles & Carey, 1997).

In a landmark study on the role of genotype affecting children's violent behavior, Caspi et al. (2002) found that a functional polymorphism in the gene encoding for monoamine oxidase A (MAOA), a neurotransmitter-metabolizing enzyme, played a role in the onset of aggression among maltreated children. Specifically, Caspi and colleagues found that among maltreated children, those who also had a short variant of the gene (which resulted in less MAOA) were more likely to behave aggressively than were maltreated children with the long variant. MAOA is known to metabolize dopamine, norepinephrine, and 5-HT which are neurotransmitters that may play a role in aggressive behavior (Buckholtz & Meyer-Lindenberg, 2008; McEllistrem, 2004).

Among early adolescents, Benjet, Thompson, and Gotlib (2010) found a significant interaction between relational peer victimization and 5-HTTLPR (a genetic polymorphism in the promoter region of the serotonin transporter gene) predicting depression symptoms in girls. They found that relational victimization predicted depression symptoms for girls with the short-short allele but that this relationship did not hold for girls who had the long-long allele or a heterozygous allele (e.g., short-long). Sugden et al. (2010) also found that 5-HTTLPR moderated the relationship between peer victimization and the development of emotional problems such that the relationship between peer victimization and emotional problems was strongest for children with the short-short allele of 5-HTTLPR.

We should note that the research examining the relationship between bullying involvement and genetics is *not* suggesting that all individuals with a particular genetic make-up will be involved in bullying or will experience the negative outcomes (e.g., poor mental or physical health) associated with bullying involvement. Rather, this research is highlighting a risk factor that may put some individuals at higher risk for bullying involvement or for experiencing negative health outcomes if they are involved in bullying.

COPING STRATEGIES

As discussed above, involvement in bullying (especially as a victim of bullying) is typically considered to be a stressful experience. Coping is defined as the cognitive and behavioral attempts to reduce or manage demands elicited by a stressor (e.g., Folkman, 1984). It is worth noting that these attempts at managing demands are considered coping even if such attempts are unsuccessful in reducing or managing demands. When youth perceive their bullying involvement as stressful, they are likely to employ coping strategies; when youth do not perceive their involvement in bullying as stressful, they are not likely to utilize coping strategies. Coping occurs in several stages. First, individuals make primary appraisals in which they evaluate the stakes of the stressful encounter. For example, children may evaluate whether a particular case of bullying is occurring in front of the larger peer group (a high stake encounter) or in a dyad or small group (a lower stake encounter). Second, individuals make secondary appraisals in which they consider their options for coping (e.g., walk away, ignore bully, problem-solve). Finally, individuals implement a coping strategy. Coping strategies are selected based on primary and secondary appraisals as well as the expected outcome.

Coping has been classified as emotion-focused (i.e., regulating emotions and reducing feelings of distress) versus problem-focused (i.e., altering the environment or situation) as well as approach/active versus avoidance/passive coping. There is evidence that the type of coping utilized by children who are peer victimized predicts children's mental health and adjustment. For example, 4th grade boys who actively coped with peer victimization by trying to resolve the problem on their own were more likely to be rejected by their peers than non-victimized boys using the same coping strategy (Kochenderfer-Ladd & Skinner, 2002). This finding suggests that problem-solving may not always be the optimal coping strategy for children who experience peer victimization. Interestingly, seeking social support acted as a buffer from social problems for girls who were peer victimized but put boys who were peer victimized at risk for social problems (compared with non-victimized children). Ignoring problems or distancing oneself from the problem were also not effective coping strategies for children who were peer victimized; these strategies predicted higher levels of loneliness and anxiety. Interestingly, peer victimized boys who used distancing were buffered from social problems (e.g., peer regard). These findings suggest that the effectiveness of coping strategies may vary for girls and boys. Moreover, coping strategies that buffer peer victimized children from social problems may not reduce the risk for mental health and adjustment problems.

Kanetsuna, Smith, and Morita (2006) asked high school students (grades 8, 9, and 10) in England and Japan open-ended questions about what they should do if they encountered bullying. In general, students suggested that victims of bullying should seek help or directly challenge the bully. However, Kanetsuna and colleagues noted that different coping strategies were suggested for different types of peer victimization experiences. For example, students suggested avoiding bullies who used physical aggression but ignoring bullies who used verbal aggression.

Although youth are often advised to tell someone if they are being bullied, Fekkes, Pijpers, and Verloove-Vanhorick (2005) found that approximately 25% of children who were regularly peer victimized did not tell an adult. According to Kanetsuna, Smith, and Morita (2006), high school students believed that victims did not tell adults because (1) they are afraid the bullying will get worse, (2) there is no one who they trust, (3) they are not confident or assertive enough,

or (4) they believe there is nothing that can be done about the bullying. Youth may be justified in their doubt that adults are able to effectively reduce the bullying. The majority of teacher candidates viewed bullying as an important problem and would recommend that victims of bullying tell teachers and parents about their bullying experience (Nicolaidis, Toda, & Smith, 2002). However, although most teachers felt confident about interacting with victims of bullying, they felt less confident about addressing the bully and helping reduce bullying. Students reported that teachers effectively stopped bullying in only 50% of cases they knew about (Fekkes, Pijpers, & Verloove-Vanhorick). Children classified as bullies reported that only approximately 52% of teachers and 33% of parents talked to them about their bullying behaviors.

The above research indicates agreement among teachers and school-aged children that victims of bullying should report the bullying to a teacher or parent. However, the research also indicates that both new teachers and school-aged youth question the ability of teachers to effectively address and stop bullying. It is not surprising that new teachers are unsure how to address bullying given their low confidence in talking directly to the bully. Moreover, the literature on coping indicates that some coping strategies may buffer against some negative outcomes (e.g., social problems) without reducing other negative outcomes (e.g., mental health, adjustment).

CONCLUSION

It is well accepted that bullying involvement as either a bully, victim, or bully-victim is associated with both mental and physical health problems. The literature reviewed suggests that bully-victims and victims are at highest risk for mental health problems. The current literature also suggests that victims of bullying are at highest risk for physical health problems. However, little research has examined the physical health problems associated with bully-victims. We encourage researchers to include students classified as bully-victims when examining the relationship between bullying involvement and physical health.

There is a large body of literature examining protective and risk factors of bullying involvement. In this chapter, we reviewed several protective and risk factors that we considered especially important when examining the association between bullying involvement and health problems. Children who have positive social relationships, both with their peers and with their parents, seem to be buffered from the negative health outcomes of bullying involvement. There is mixed evidence on whether personality and individual differences influence the relationship between bullying involvement and health outcomes, but it is clear that personality and individual differences predict both social relationships and mental/physical health separately. Physiological functioning (e.g., brain activity, hormones) and genetics may also influence the relationship between peer victimization and health outcomes by placing individuals at higher risk for poor health outcomes if exposed to bullying.

Finally, we considered how youth may respond to peer victimization through various coping strategies. From the current literature, it is not yet clear what the optimal or most effective coping strategies are to use when peer victimized. Although some coping strategies help reduce social problems, these same strategies do not seem to protect youth from mental health problems. It is worthwhile to examine whether supplementing such coping strategies

with therapy may help reduce mental health problems and alleviate feelings of loneliness and anxiety in victims of bullying. In addition, more empirical evidence is needed to inform teachers and other adults how to respond when youth report experiencing peer victimization. Although both youth and teachers agree that “telling someone” is one of the most widely suggested and used coping strategies, many teachers do not feel equipped to directly address the bully.

We assert that bullying in schools is a complex phenomenon. Reducing school bullying requires a multidimensional, multidisciplinary approach. Indeed, it is necessary to consider (1) the personality of involved students, (2) previous bullying involvement (e.g., length of involvement), (3) amount and quality of social support from peers, teachers, and parents, and (4) home environment (e.g., parenting style). In addition, understanding genetic predispositions and physiological functioning may provide additional information regarding who is at higher risk of experiencing mental and physical health problems when involved in bullying.

Chapter 92

THE IMPLEMENTATION OF A STATEWIDE BULLYING PREVENTION PROGRAM AND ITS IMPACT ON SCHOOLS AND COMMUNITIES

Shiryl Barto and Matthew Masiello***

Center for Health Promotion, Windber Research Institute,
Windber, Pennsylvania, US

ABSTRACT

Purpose: To reduce bullying by producing a quantifiable change in school climate by the end of the three-year implementation period using an established measurement tool. **Design:** An age-cohorts design was used. Data from two equivalent age cohorts of students are compared at two or more points in time. Seven school buildings with delayed program implementation were used as a control. **Setting:** Public school districts in 49 counties across Pennsylvania. **Subjects:** 56,137 students and over 2,400 teachers from 107 schools. **Measures:** The Olweus Bullying Questionnaire was administered to students in HALT! and PA CARES The Teacher Questionnaire was administered to teachers in selected HALT! schools. **Analysis:** Data from two equivalent age cohorts of students are compared at two or more points in time. **Results:** Across cohorts, there were reductions in student self-reports of bullying others; and improvements in student perceptions of adults' responsiveness, students' attitudes about bullying, and teachers' attitudes about bullying. **Conclusions:** This study is the largest bullying prevention initiative to date in the US. By bringing together several stakeholders, it reaffirms the efficacy of the OBPP, as well as highlighting several new outcomes.

INTRODUCTION

The health and social issues related to bullying are significant, costly, and have long term effects. Bullying is defined as a person being repeatedly exposed to negative actions on the part of one or more other persons and has difficulty defending him or herself (Olweus, 1993).

Bullying is also described as a “systematic abuse of power” (Smith, 2004). Though the high-level school violence associated with the use of weapons and death captures the attention of the public, it is bullying or low-level violence defined as peer aggression in the form of teasing, rumors, intimidation, and physical confrontation that affects approximately 20-30 percent of students on a daily basis (Meyer-Adams, 2008). Depression, suicidal thoughts, substance abuse, and an increased predilection to crime are negative consequences associated with bullying (Olweus.org, 2008; AMA, 2002; Limber, 2006; Gini & Pozzoli, 2009). Without intervention, bullies in middle school are three times as likely to have at least one criminal conviction by the age of 24 (Olweus, 2005). In the classroom setting, students involved with chronic bullying feel unsafe, lack a sense of personal and academic satisfaction, and become fearful and apathetic (Blueprints, 2002.; Olweus.org, 2008). Over time, the student observers of bullying have a decreased sense of empathy for other students (Blueprints, 2002). These bystanders may feel unsafe and have difficulty learning (Olweus.org, 2008). Lower academic achievement, higher drop-out rates and school absenteeism are additional burdens placed upon students, schools, parents, and society (Limber, 2006). Studies by the U.S. Secret Service and Department of Education revealed that nearly 75 percent of the attackers in school shootings indicated that they were bullied or otherwise hurt by their peers prior to the shootings (Crawford, 2002). One of the largest U.S. studies on bullying was conducted in 1998 when approximately 15,000 students were surveyed. It defined bullying in the United States of America from the perspective of school grade occurrence, gender specific bullying traits, and social strata prevalence. This report, along with European studies, provided a basis for future USA-based program activity and research (Espelage, 2004).

The health consequences of bullying are well documented. Researchers found that there was an association between children who were bullied and incidences of not sleeping well, bed wetting, feeling sad, headaches, and “tummy” aches (Williams, 1996); this same study found that there was an increased risk of symptoms with increased frequency of bullying. A meta-analysis of peer victimization studies found that victimization is significantly positively associated with depression (Hawker, 2000). These psychosocial difficulties further increase the risk of victimization and are found across sex and ethnic groups (Nishina, 2005). Interestingly, psychosomatic problems are not just limited to victims of bullying. Indeed, children who bully showed higher risk of externalizing problems, poor school adjustment, and frequent drug and alcohol use, while children who were both bullies and victims were at high risk for being poorly social adjusted, isolated, anxious, hyperactive, and having altered personalities (Gini, 2009). Additionally, bullies and bully/victims are at increased risk for both smoking and drinking when compared to uninvolved peers (Vieno, 2011).

All these health impacts take a toll on the immediate and long term health of bullies, victims, and bully/victims. They also end up costing society as a whole. A cost-benefit analysis based on published data found that the cost of bullying-related health conditions (e.g., mental health disorders, headaches, abdominal pain, alcohol abuse, etc) per student ranged from \$609 to \$3,567 (Zema, unpublished).

With the consequences of bullying fairly evident, the next question becomes what to do about it. The World Health Organization’s Violence Prevention Alliance (VPA) uses the principles of public health as a framework for understanding and preventing violence. By definition, public health aims to provide the maximum benefit for the largest number of people. A public health approach to bullying prevention consists of systematic collection of information about the problem; using research to determine the causes and effects of the problems; finding

out what works to address the problem through designing, implementing, and evaluating intervention; and implementing effective interventions in a wide range of settings while monitoring and evaluating the outcomes' impact and cost-effectiveness (WHO.int, 2012).

Since the 1970's, the bullying prevention work of Dan Olweus has been the only program to systematically examine the prevalence and social issues surrounding bullying (Smith, 2004). The Olweus Bullying Prevention Program is the most widely accepted, internationally recognized, evidenced-based health promotion program developed to address the most common form of violence in society: school-based bullying. The Olweus model is reported to reduce school-based bullying by 30-50 percent in schools that implement the program with fidelity. Supporting wide-scale adoption of the program by schools is a strategic component in bullying reduction efforts. The Olweus Bullying Prevention Program (OBPP) uses four areas of concentration to enable schools to address bullying systemically:

1. School-wide measures that focus on the training of the entire school staff, including a coordinating committee whose work drives the program in each building. School rules against bullying are posted throughout the school and students are surveyed yearly using the Olweus Bullying Questionnaire (OBQ).
2. Classroom measures that include discussion, class meetings, role-playing and enforcement of school rules against bullying.
3. Individual components of OBPP to help guide a school's response and cover on-the-spot interventions, follow-up meetings with the student who is bullied and the student who is bullying along with increased parental engagement.
4. Community participation, which involves the involvement of local government, law enforcement, community agencies, media and other community partners who may provide valuable time, resources and information toward the success of the program. Spreading the anti-bullying message outside the walls of the school is an essential OBPP component.

In 2007, the Highmark Foundation, based in Pittsburgh, introduced to Pennsylvania schools two bullying prevention programs based on the Olweus program, HALT! and PA CARES (Creating an Atmosphere of Respect and Environment for Success), and established the Highmark Healthy High 5 Bullying Prevention Institute (BPI). The objectives of these programs are to bring effective and evidence-based bullying prevention strategies to schools and communities without current intervention, and to monitor and evaluate the results of these programmatic implementations (Schroeder, 2012).

METHODS

The Center for Safe Schools in Camp Hill, Pennsylvania manages PA CARES. HALT! is managed by the Center for Health Promotion and Disease Prevention (CHPDP) at Windber Research Institute (WRI), Windber, Pennsylvania. The Highmark Bullying Prevention Institute is managed by the CHPDP.

Since its inception in 2007, PA CARES has worked to build local school readiness and capacity for implementing successful intervention strategies within schools in Highmark

service areas and across the Commonwealth. PA CARES supports schools in their efforts to create safe learning environments, using a school building-level, mini-grant approach to deliver the OBPP. This program integrates traditional training and communication tools, web-based technologies, and other activities designed to support research-informed practice. PA CARES expands the number of certified OBPP trainers and coaches who provide professional development training to schools. Trainers also track model implementation to support evaluation of bullying prevention efforts. This comprehensive approach puts timely, accessible bullying prevention information and research into the hands of certified trainers, school personnel and community practitioners. The PA CARES initiative builds capacity for ongoing bullying prevention through web-based and face-to face activities. There are data for three cohorts of schools supported by PA CARES.

HALT! focused on implementing the OBPP on a district wide basis. The overall mission of HALT! is to bring effective, evidence-based bullying prevention strategies to schools and communities without current intervention; educate students, parents and faculty about the issues surrounding bullying; enhance the school climate toward a more pro-social model for all children; enhance the effectiveness of teacher and parent bullying behavior intervention; and create targeted regional “centers of excellence” in bullying prevention to provide best practice examples and resources for all schools. There are data for three cohorts of schools supported by HALT!

Interested school districts notified WRI of an intention to participate in HALT! OBPP trainers then met with the districts’ administrators and teachers to determine feasibility and readiness. If the district was ready to implement, school administrators signed a memorandum of understanding that outlined a three-year commitment to fully implement OBPP and fulfill evaluation requirements. Districts that participated in HALT! received OBPP materials, including the OBQ and other survey tools that assess bullying prevalence and school climate. OBPP Coordinating Committee and staff trainings and weekly on-site consultation with a certified Olweus trainer are also a part of first-year assessment. Up to 20 districts which were located in within the Foundation’s service area are invited to participate. The regions include Allegheny County area, Erie area, Southwestern PA, and York/Harrisburg.

HALT! provided certified Olweus trainers to offer intensive, ongoing support to participating districts throughout the first year of implementation. To help elicit high rates of fidelity and sustainability, technical assistance and program materials were provided throughout a three-year implementation period.

PA CARES selected individual school buildings within school districts in which to implement its program; The HALT! program provided support to public school districts that comprise many school buildings rather than individual buildings. Only public school districts that had not previously implemented the Olweus model were eligible to participate in HALT! Approximately 100,000 students across Pennsylvania participated in either HALT! or PA CARES.

The initial goal of the Highmark Bullying Prevention effort was to produce a positive change in school climate by the end of the three-year implementation period. Examples of impact on school climate include the student’s perceptions of their teacher’s effectiveness in preventing and intervening in bullying situations, the rate at which students actively intervene in support of their peers, the rate that students express fear of being bullied, and the students’ perceptions as to how much they enjoy school. The shift in the school climate is demonstrated in the primary work of Dan Olweus, Ph.D.

For purposes of this study, a measure of relative change (Olweus & Limber, in press) was used, which is calculated as the difference in percentages between the baseline (initial) assessment prior to program implementation, and subsequent assessments. As an example, if the percentage of bullied students in elementary school is 20% at Time 1 (baseline) and 15% at Time 2 (after 3+ months of implementation), the relative change score will be 25% $[(15-20)*100/20 = -25\%]$. An age-cohorts design (Olweus & Limber, 2010) was used to analyze program effects. Data from two equivalent age cohorts of students are compared at two or more points in time (pre-implementation and post-implementation). Measures used included the Olweus Bullying Questionnaire (OBQ, 2007), which was administered to students in the HALT! and PA CARES cohorts and the Teacher Questionnaire (2008) to teachers in selected HALT! and PA CARES schools. The OBQ measures bullying problems, student attitudes regarding bullying, how other students react to bullying, and students' general feelings about school.

The OBQ consists of 42 multi-part questions that collects data on bullying problems, attitudes regarding bullying, bystander perceptions of bullying, and general satisfaction with school. Some of the key hallmarks included student reports of being bullied, student reports of engaging in bullying behavior, students' perception of adult attitudes, students' attitudes about bullying, and students' perception of teachers' responsiveness to bullying.

RESULTS

Overall, student self-reports of bullying others were reduced among nearly all cohorts and age groups. Results appeared to be particularly positive among high school students, where reductions were observed in bullying others of 15 to 39 percent, depending upon the specific cohort. However, mixed findings were seen in students' self-reports of being bullied, with some age groups and cohorts showing decreases and others showing no positive program effects.

Almost universally across age groups and cohorts, positive changes were observed in students' perceptions that adults in the school were actively working to address bullying. When students were asked how much their teacher had done to address bullying, there was an 11 – 53% reduction in the numbers of students who responded that their teacher had done little to address bullying.

Across most groups, increases were observed in the percentage of students who indicated they would try to help a bullied student, and decreases in the percentage who felt they would passively observe or join in bullying. For example, after two years of implementation, 27 percent more elementary students (from HALT! schools) said they would try to help a bullied student.

Very positive findings were observed regarding elementary, middle, and high school teachers' perceptions of bullying and activities to address bullying at school after one year of OBPP implementation. For example, there were marked and statistically significant increases (ranging from 14-131 percent) among elementary, middle, and high school teachers in the likelihood that they regularly (2 or more times per month) talked with their classes about bullying.

Consistently positive and significant increases were observed in elementary, middle, and high school teachers' perceptions that their schools' rules and policies about bullying had been

clearly communicated to students (ranging from 17-69 percent), parents (ranging from 14-81 percent), teachers (ranging from 19-30 percent), and other staff (19-34 percent).

In high schools, there were positive intervention results for student reports of being bullied, bullying others, perceptions of adult responses to bullying, and attitudes about bullying.

Data from the HALT! Cohort 1 schools reveal that many program effects are stronger after two years of implementation than one. These findings are consistent with those of other studies that have observed the implementation of OBPP as an ongoing process (Olweus, 1993; Olweus & Limber, 2010).

At the end of 12 or more months of implementation of the OBPP in Cohort 1 HALT!, elementary and high schools, positive findings observed included significantly decreased reports of students bullying others and the perception that teachers were doing “little or nothing” to prevent bullying in both elementary and high schools. In addition, high schools had significantly decreased reports of students being bullied (Fig 1). There was a reduction in reports of bullying others among elementary students, although this decrease was not statistically significant. Significant decreases were observed in most specific forms of bullying.

After three or more months of implementation of the OBPP in Cohort 2 HALT!, elementary, middle, and high schools showed positive findings. Elementary, middle, and high schools had significantly decreased reports of bullying others and the perception that teachers were doing “little or nothing” to prevent bullying. Middle and high schools had significantly decreased reports of students who believed they could join in bullying, and elementary and middle schools had significantly increased reports of students who would try to help a bullying victim (Fig 2).

After three or more months of implementation of the OBPP in PA CARES, elementary, middle, and high schools showed positive results as well. Elementary schools reported an increase in students being bullied however, elementary, middle, and high schools all showed decreases in reports of bullying others and perceptions that teachers were doing “little or nothing” to prevent bullying. There were also increased reports of students who would try to help a bullying victim in elementary, middle, and high schools (Fig 3).

CONCLUSION

For both HALT! and PA CARES, there were positive intervention results for student reports of being bullied, bullying others, perceptions of adult responses to bullying, and attitudes about bullying. Data from the HALT! Cohort 1 schools reveal that many program effects are stronger after two years of implementation than one. These findings are consistent with those of other studies that have observed the implementation of OBPP as an ongoing process (Olweus, 1993; Olweus & Limber, 2010). It is not only important to see decreases in students’ reports of being bullied and bullying others, but it is also to observe changes in students’ perceptions of adults’ responsiveness to the implementation of the OBPP elements. In addition, a more positive school climate is created by decreasing the percentage of students who are “bystanders” when they see bullying occur and by increasing the percentage of students who actively try to help the bullied students (Limber 2006).

Across the nation, this Pennsylvania-based bullying prevention initiative serves as the largest and most comprehensive effort to date to systematically and strategically address this public health issue. This Pennsylvania group is the largest cohort of children in the world who have been evaluated in order to determine the effects of a bullying prevention initiative. As a result of the efforts of the Highmark Foundation and its partners, this study offers the largest coordinated implementation and evaluation of the OBPP in the United States. Data represents

the first pilot of the OBPP in high school settings in the United States. With the scale and scope of Highmark's investment, several new outcomes were realized. Highmark's Healthy High 5 bullying prevention effort will impact approximately 210,000 students, or 13 percent of all public and private school students within Highmark's service area.

Results from this project indicate that the OBPP can be implemented particularly successfully in large populations when strategic community partners are identified and established. Schools, if left unsupported, may be unable to sustain these efforts on their own over time. Highmark's state- and district-wide approach has enhanced partnerships between schools, districts, and institutional coordinators (Windber Research Institute and the Center for Safe Schools). By providing a high level of technical support to schools, partnerships have helped to facilitate successful implementation of the OBPP.

Particularly promising are initial results from students in participating high schools. These findings underscore the need to further understand the current application of the OBPP in high school settings and to develop ways to tailor and improve this implementation. This study's preliminary results indicate an area of further investigation regarding differences between teacher and student perceptions of bullying behavior and the need for bullying prevention in high schools.

To the extent that a high level of fidelity to OBPP implementation is linked to positive program outcomes, a continued focus on assessing OBPP fidelity is needed. Understanding the link between fidelity of implementation and program outcomes in elementary, middle, and high schools is necessary. Thus, a system is needed to certify the varying degrees of fidelity with which OBPP schools implement the program.

Continuing education which has been available to trainers, parents, teachers and administrators, has likely had an important impact on fidelity of the program. Collective experiences gained from the project have a direct relationship to long-term sustainability.

As a result of Highmark Foundation's Bullying Prevention effort, a recertification process was developed for Olweus Trainers in Pennsylvania. The standardization of training offered to schools insures that the most recent and up-to-date research and resources in the field are shared. Sharing results in more consistent outcomes. The recertification process developed with Highmark funding will serve as a model program for other states.

PA CARES and HALT! demonstrated that undertaking pre-implementation assessment is related to consistent implementation of the program. It is necessary for schools to assess their readiness to implement a bullying prevention program. This pre-implementation assessment involves securing administration and faculty support prior to beginning a project. Highmark Foundation supported initiatives have gone beyond standard pre-implementation assessments of similar studies.

Year two data from HALT! Cohort 1 supports the need and importance of implementing OBPP over two or more years, permitting analysts to observe continued improvement in bullying prevention outcomes. The role of the teacher in bullying prevention cannot be understated. Although it is the responsibility of teachers to communicate rules to their students, the onus typically is on administrators and/or members of schools' coordinating committees to communicate rules to teachers, other staff, and parents. From an outcomes perspective, it is highly encouraging that teachers feel that their leaders have done an exceptional job in this regard. The increased dialogue between teachers and students about bullying is consistent with previous studies. This finding is encouraging, as holding regular class meetings about bullying is a core component of the OBPP. Class meetings are the venue through which much

information about the program and the schools' expectations are delivered to students and a time where community-building occurs. Seeing positive change in middle and high schools is particularly encouraging, as schools at these levels frequently have difficulty finding time for these important discussions.

One of the keys to the success of this project was identifying key partners and forging successful collaborations. A bullying prevention coalition was established, including the Highmark Foundation, the Pennsylvania Center for Safe Schools, Clemson University, the Pennsylvania Department of Education, Windber Research Institute, and the University of Bergen. This coalition provided expertise, funding, support, and "best-practices" sharing for this initiative. By collaborating among this diverse group of partners, it was possible to have a positive impact on the behavior and physical health outcomes of a large population of children and adolescents (Schroeder, 2012).

The impact data from this school and community-based prevention initiative, in response to the well-documented negative health and social effects of bullying, has clearly demonstrated the importance of adherence to prevention science and to identifying key partnerships.

Through the Highmark Foundation's comprehensive and strategic approach to program implementation, partnerships, and evaluation, a cultural change has come about in participating schools. Bullying is now an understood behavior that no longer will be tolerated. Bullying can no longer disrupt an educational environment. Through efforts like that of the Highmark Foundation, bullying prevention initiative is working.

ABSTRACT

Bullying is a multifaceted phenomenon and is connected to a variety of individual, relational, familial, schooling, and cultural variables.

This chapter aims to explore the relationship of school bullying with personal values, exposure to interparental and community violence, and emotional states. We explored four main hypotheses: i) exposure to community and interparental violence predict the involvement in school bullying both as a victim and bully; ii) personal values of self-transcendence and self-enhancement predict the involvement in bullying behaviour (negatively and positively respectively); iii) involvement in school bullying, both as a victims and bully, predict emotional experiences of fear, anger, sadness, and serenity; iv) school bullying mediates the relationship between values, family and community violence and emotions, increasing the amount of negative feelings. A unitary pattern of these relationships was tested through a structural equation model.

The study was performed in five cities of south of Italy.

The sample was made up of 3426 subjects, (mean age= 15.24; ds= 2.60; range 11-19), attending 7th, 10th and 13th grade classes, distributed in 34 schools and 206 classrooms.

Participants filled out a questionnaire containing measures concerning self-transcendence and self-enhancement values, exposure to community violence, exposure to interparental violence, emotional states of anger, fear, sadness and serenity, and involvement in school bullying as a bully or victim.

To test the hypotheses regarding the relationships among values, exposure to interparental violence, exposure to community violence, bullying and emotions, we used

* Corresponding Author's Email: dario.bacchini@unina2.it

gender and age multi-group Structural Equation Modeling (SEM) analyses. Findings show good indexes of fit for the hypothesized model.

More specifically, without distinction for gender or age, bullying and victimization are predicted by exposure to community and interparental violence, bullying others is predicted by self-transcendence (negatively) and self-enhancement (positively) values, in turn bullying others predicts (positively) emotional states of anger, while victimization predicts (positively) emotional states of anger, fear, sadness, and (negatively) of serenity.

The results of the study provide useful indications for programmed intervention, suggesting the need to prevent school bullying through school programs.

Keywords: school bullying, personal values, exposure to community violence, interparental violence, emotional states

OVERVIEW

A large number of studies carried out during the last three decades have produced strong evidence that school bullying is a pervasive phenomenon that involves students of all ages, genders, and socio-cultural backgrounds. The social alarm generated by studies on school bullying has increased the interest of scholars and professionals very impressively (Berger, 2007), developing a wide range of research aiming to understand the most significant correlates of school bullying - antecedents and consequences - and the factors that can promote effective school interventions.

There is wide agreement that, within an ecological and multi-factorial perspective, school bullying has to be considered a multifaceted phenomenon which is connected to a variety of individual, relational, familial, schooling, and cultural variables.

Nevertheless, few studies have simultaneously considered these different levels of explanation (Hong & Espelage, 2012), and these studies have not analyzed the predictors of school bullying and the consequences of bullying on the emotional well-being of the subjects involved simultaneously.

The research we present in this chapter has the purpose of furthering the research on school bullying, considering two classes of antecedents that have rarely been examined in previous research: personal values and the exposure to interparental and community violence. At the same time, this research aims to analyze the effects of bullying others or having been bullied by peers on the resulting emotional experience. The interconnections between personal values, exposure to violence, school bullying, and emotional experience, will be analyzed within a more complex model that includes direct and indirect influences.

PERSONAL VALUES AND BULLYING

Values are desirable, abstract goals that apply across situations; they serve as guiding principles in people's lives and as criteria to select and justify actions and to evaluate people and events (Rokeach, 1973; Schwartz, 1992). Yet, although values play an important role in understanding and predicting beliefs, attitudes and behaviors, their popularity as a research topic has varied over time. In the last twenty years, the most accredited model has been

Schwarz's theory of the structure of values (Schwartz, 1992; 1994), which has been the object of more than 200 studies in over 75 countries.

Although some studies have shown a direct association between values and aggressive behaviors, few studies have been carried out to analyze the role of personal values on bullying behavior.

A starting point from which to investigate this relationship is the debate on the nature of bullying that took place at the end of nineties, with the opposition of Crick and Dodge (1999), who saw the bully as lacking in social skills, and Sutton, Smith and Swettenham (1999a; 1999b), who argued that bullies were highly socially skilled and used their social knowledge to attain their goals. Through this debate, the contribution by Arsenio and Lemerise (2001) is of fundamental importance because these authors introduced the need to study the values of bullies to understand the phenomenon of bullying. They claimed that social competence cannot be defined in a value-free way because it can be used in either a prosocial or an antisocial way, depending on the values held by the individual. In this way, bullying can be considered a socially competent behavior because it allows the individual to attain his goals, and a critical issue in understanding bullying will be to consider the values of bullies; in other words, the way in which they evaluate the costs and benefits of aggression (Arsenio&Lemerise, 2001).

In any case, few studies have empirically evaluated the goals or values of bullies.

Some studies (e.g., Unnever& Cornell, 2003) indirectly examined the relationship between bullying and values taking into account attitudes toward bullying that could be considered an indirect expression of personal values. If positive attitudes, convictions, and beliefs about bullying are widely shared inside a school, then the presence of a "culture of bullying" can be discussed. In other words, a culture of bullying is a multidimensional phenomenon that is characterized by a normative set of shared beliefs that support or encourage bullying behaviors (Smith & Brain, 2000).

As for the goals associated with bullying – a concept very close to that of values – Sijtsema, Veenstra, Lindenberg and Salmivalli (2009) measured the status goals of bullies. They found that bullies attribute great importance to these goals because they use aggression to reach dominance and prestige inside the social group.

As regards the values of bullies, some studies have linked bullying behavior and values as conceptualized in the "theory of the universal structure of human values" (Schwartz, 1992, 1994); this theory is also the conceptual framework used in the present study and postulates the existence of ten universal values that can be grouped into four broader dimensions: self-enhancement (power and achievement), self-transcendence (universalism and benevolence), openness to change (self-direction and stimulation) and conservation (tradition, conformity and security); the value of hedonism shares elements of both self-enhancement and openness to change.

One of the few studies that linked values and bullying (Knafo, 2003) showed that teenage boys who adopt bullying behaviors with high frequency attach higher priority to the value of "power", which in Schwartz's theory is defined as attempting to attain "social status and prestige, control or dominance over people and resources" (Schwartz, 2006).

Another study based on Schwartz's theory, which compared traditional bullying and cyberbullying (Menesini, Nocentini&Camodeca, 2011), showed that self-transcendence had a negative direct impact on traditional bullying whereas self-enhancement and openness to change had a positive impact on this type of aggression even if these effects were indirect and acted through the mediation of immoral behavior. Therefore, values oriented towards the

welfare of others, such as those that are classed as self-transcendent, appear to act as protective factors against bullying; on the contrary, self-oriented values, such as those of the self-enhancement class, and values that promote the search for exciting sensations and strong emotions, such as those that are classed among openness to change, appear to favor the implementation of bullying behaviors (Menesini et al., 2011).

Gender differences in the relationship between values and bullying exist; Ojanen, Aunola, and Salmivalli (2007) found that male bullies attributed higher importance than females to status goals, which can be considered part of self-enhancement in Schwartz's classification. This difference, however, has not been found in the study by Sijtsema et al. (2009). Menesini et al. (2011) also found no gender differences.

Some authors argue that the relationship between values and bullying becomes stronger in adolescence; in childhood, bullying would be less strategic and more immature (Sijtsema et al., 2009).

Although the literature regarding the relationship between bullying and values - or life goals - is small, the number of studies evaluating the values of victims is even smaller. Among these very few studies, Sijtsema et al. (2009) also measured the goals of victims and found that victims attribute low importance to status goals.

Regarding the emotional experience (the other topic of our study), which is considered a proximal indicator of psychological well-being and mental health, few studies have examined the links between values and well-being. Bilsky and Schwartz (1994) found that well-being was positively associated with benevolence, universalism, achievement and stimulation (as these promote the personal growth of the individual) and negatively associated with power, conformity and security. Moreover, Kasser and Ahuvia (2002) found a positive association between well-being and "intrinsic" values (such as benevolence, universalism and self-direction) and a negative association with "extrinsic" values, such as power. According to this field of research, the existence of absolute "beneficial" values (which are "healthy" independently of the social context to which the individual belongs) is hypothesized. On the contrary, Sagiv and Schwartz (2000) suggest also considering the role of congruence between the values of the individual and those of the social environment in which he lives in determining subjective satisfaction. In conclusion, the relationship that exists between values and mental health remains unclear.

EXPOSURE TO INTERPARENTAL VIOLENCE AND BULLYING

In recent decades, researchers, clinicians, and policymakers have expressed increasing concern that children who are exposed to interparental violence may suffer negative consequences even when the targets of violence are not themselves (Osofsky, 1995). Child exposure to domestic violence is associated with a wide range of mental health symptoms (e.g., Fantuzzo & Lindquist, 1989; Kolbo, Blakely, & Engleman, 1996; Wolak & Finkelhor, 1998). More specifically, children exposed to domestic violence report more depressive symptoms, anxiety, and worry than those who have never been exposed to such violence (e.g., Graham-Bermann, 1996; Spaccarelli, Sandler, & Roosa, 1994; Sternberg, Lamb, Greenbaum, Cicchetti, Dawud, Cortes et al., 1993). These children also appear to be more prone to physical aggression

and have higher levels of general behavior problems, when rated by parents and teachers (Sternberg, Lamb, Guterman, & Abbott, 2006).

Although many studies have been carried out that analyze the relationship between familiar variables and involvement in school bullying, few of these have investigated the association between bullying and exposure to family violence. As CorvoanddeLara (2010) affirm, “In the academic literature and in the arenas of practice (schools, clinics, shelters, etc.), bullying and domestic violence have been considered as largely unconnected phenomena” (p.182). Specifically Baldry (2003), in a study conducted with an Italian sample of elementary and middle school students that used the Conflict Tactic Scales (Straus, 1979), found that family violence was a significant predictor for both bullying and victimization. Violence by the father against the child and violence by the mother against the father were two independent predictors of bullying and victimization after controlling for other variables of violent behavior within the family. Models for bullying and victimization both showed that exposure to parental violence (especially that by the mother against the father) significantly predicted bullying and victimization, over and beyond age, gender, and parental harming of the child. However, the two models predicted a higher proportion of variance for bullying than victimization, and the effects of interparental violence were higher for females than for males.

Bauer et al. (2006) also examined the relationship between childhood behaviors and exposure to intimate-partner violence at home using a community-based sample of 112 children aged 6–13. The authors found only a moderate relationship between interparental violence and bullying involvement, and this association disappeared after controlling for a series of confounding variables; however, intimate partner violence-exposed children were at increased risk for problematic levels of externalizing behaviors, physical aggression and internalizing behaviors.

Another study, which was conducted on a sample of underage psychiatric inpatients, found that witnessing interparental violence increased the risk of being a victim of bullying among boys; for girls, being a victim of a violent crime was a risk factor for being a bully-victim (Mustanoja, Luukkonen, Hakko, Räsänen, Säävälä, & Riala, 2011).

EXPOSURE TO COMMUNITY VIOLENCE AND BULLYING

A large body of research has shown that high levels of exposure to violence during development promote maladaptive psycho-social behaviors and a wide range of mental health outcomes.

Specifically, youths who have been exposed to community violence report higher symptoms of post-traumatic stress disorder and internalizing disorders (Bacchini, Miranda, & Affuso, 2011; Gorman-Smith, Henry, & Tolan, 2004; Ho, 2008; Kliwer, Lepore, Oskin, & Johnson, 1998), academic failure (Henrich, Schwab-Stone, Fanti, Kones & Ruchkin, 2004), socio-cognitive biases in processing social information (Shahinfar, Kupersmindt, & Matza, 2001) and, above all, aggressive behaviors and externalizing symptoms (Barkin, Kreitetr, & DuRant, 2001; Scarpa, 2001; Su, Mrug, & Windle, 2010).

The mechanisms through which exposure to community violence affects child adjustment are varied. Exposure to violence can act as a proximal factor of risk; individuals who live in a high-crime neighborhood tend to adopt an aggressive stance (McIntyre, 2000). In most cases,

however, exposure to violence does not influence externalizing behaviors directly but indirectly through mediating and moderating variables such as social cognitions (Shahinfar et al., 2001), attitudes to violence (Su et al., 2010), parental nurturance (Gorman-Smith, Henry & Tolan, 2004; Proctor, 2006).

Despite the interest of developmental researchers in this subject, relatively few studies have investigated the relationship between school bullying and exposure to neighborhood violence (Andershed, Kerr, & Stattin, 2001; Bacchini, Esposito, & Affuso, 2009; Espelage, Bosworth, & Simon, 2000; Khoury-Kassabri, Benbenishty, Astor, & Zeira, 2004; Nansel, Overpeck, Haynie, Ruan, & Scheidt, 2003; Schwartz & Proctor, 2000; Swearer & Doll, 2001; WienkeTotura, MacKinnon-Lewis, Gesten, Gadd, Divine, Dunham, & Kamboukos, 2009)

The studies mentioned above found a positive association between neighborhood violence and bullying behaviors. Neighborhood safety concern and access to a gun were found to positively correlate with bullying behavior (Espelage et al., 2000), whereas residing in an unsafe and low-income neighborhood improved the probability of experiencing peer victimization (Khoury-Kassabri et al., 2004). In the Italian context, Bacchini et al. (2009) found that bullies and bully-victims reported having more dangerous experiences outside the school than victims or youths not involved in bullying, despite the fact that this involvement did not influence their perception of the safety of the neighborhood as they were adapted to the violent context and extended the way of life learned outside the school to the school context. By contrast, Nansel et al. (2003) found that bullying others and being bullied by others were consistently related to various forms of violent behavior outside the school (e.g., carrying a weapon, frequent fighting or being injured in a fight) for both boys and girls, even though bullying others carried greater odds of involvement than being bullied. However, an important limitation of this literature is the lack of distinction – regarding the exposure to community violence - between being a victim of and a witness to violence. Research has shown that the two experiences are strongly related, but it is important to consider both to obtain a complete picture of the behavioral, cognitive and emotional consequences. Whereas witnessing violence involves social learning processes that lead individuals to display positive attitudes toward aggressive and antisocial behaviors (Farrell & Bruce, 1997; Gorman-Smith & Tolan, 1998), being a victim of violence mainly involves affective processes that affect the capability for emotional regulation, thereby determining negative feelings toward the community.

Regarding the relationship between exposure to violence in the community and bullying in schools, Andershed et al. (2001) conducted a study in Sweden to test two alternative hypotheses: i) that bullying and victimization in school are largely restricted to the school context and not linked to violence on the streets and ii) that bullying behavior is a reflection of a more general aggressive behavior pattern, and hence, bullying in school and violence on the streets involve the same individuals.

The results of the study clearly showed that, without any distinction between males and females, bullying others in schools was strongly linked to violent behavior, weapon-carrying on the streets, and loitering on the streets and that bullying others in school was related to being violently victimized on the streets. At the same time, the authors found that bully-victims were more at risk than pure bullies. A limitation of this study is that the authors did not consider the victimization as a dependent variable, but only as a variable associated with the bullying of others.

In line with previous results, a large survey conducted in 1,000 Colombian schools (Chaux, Molano, & Podlesky, 2009) demonstrated that exposure to violence in the neighborhood

remained a unique predictor of school bullying, even after controlling for the effects using other indicators of social problems.

BULLYING AND EMOTIONAL STATES

Emotions are specific reactions to particular events that comprise several components, such as an experiential feeling, cognitions and physiological reactions, which may have important behavioral implications (Stanley & Burrows, 2001). Emotions may be seen as critical and vital signs that provide essential information regarding an individual's health and well-being (Spielberger & Reheiser, 2009) and how he perceives and reacts to his environment. Surprisingly, few studies have examined the relationship between bullying and emotional experience (Løkke, Lars, & Ståle, 2012). This is possibly because, in the past, bullying was considered by previous generations as a normal pattern of interaction among youths and thus harmless. Contrarily, current research has demonstrated that bullying and being bullied can affect various mental health problems (Arseneault, Walsh, Trzesniewski, Newcombe, Caspi, & Moffit, 2006; Juvonen, Graham, & Schuster, 2003; Nansell, Overpeck, Pilla, Ruan, Simmons-Morton, & Schmidt 2001; Veenstra, Lindenberg, Oldehinkel, De Winter, Verhulst, & Ormel, 2005). Bullies and bullied children show signs of psychological problems that can persist throughout life.

Previous research has typically focused on only one or a few affective states, thus potentially ignoring other emotions while overemphasizing those investigated. In the present study, we will therefore measure several types of potentially felt emotions adapting a well-known instrument with good psychometric qualities (PANAS; Watson, Clark, & Tellegen, 1988), thereby allowing for a more differentiated and nuanced understanding of the bullying phenomenon.

Specifically, the present study will focus on four emotional states: anger, fear, sadness and serenity.

The affective state of *anger* is the most investigated among studies of bullying.

The emotion of anger is frequently shared by bullies and victims for three different reasons: i) many subjects experience bullying and victimization simultaneously, and some studies have shown that these subjects are more likely to experience feelings of anger (e.g., Olweus, 1993, talked about a provocative victim); ii) victims tend to experience anger in reaction to being bullied but, at the same time, appear to have an inadequate way of showing and managing anger, resulting in exposure to subsequent retaliation; and iii) bullies appear, conversely, able to manage anger in a functional way; good management of anger permits them to communicate dominance over another person (Frijda, 1986; Izard, 1993).

Among the studies about bullying and anger, Champion (2009) found that both victimization and bullying were moderately but significantly correlated with the experience of anger and also observed that low anger predicted good coping strategies, like ignoring or distraction.

The role of anger as a direct consequence of victimization was investigated by Sigfusdottir et al. (2010), who tested the hypotheses that the experience of both bullying and victimization affected nonviolent delinquent behavior and that this relationship was mediated by the emotion of anger. The results demonstrated that the relationship between anger and delinquent behavior

was stronger for bullies than for victims and that the mediating role of anger was stronger for bully-victims than for pure bullies.

As regards the affective state of *fear*, it is plausible to hypothesize that fear can be associated with victimization because this is an abusive condition that occurs repeatedly over time; in victims that are not able to defend themselves from bully attacks, fear tends to rise in the presence of the bully. Conversely, bullies, who intentionally get involved in situations of conflict with other peers, tend to experience low levels of fear; in fact, the literature shows that low levels of fear reactivity put the youth at risk for aggression and related problem behaviors because they disrupt the normal development of conscience and empathy, and the internalization of social norms. In other words, youth with low fear reactivity are not distressed enough by the potential negative consequences (e.g., punishment, retaliation, or harm) or by the inappropriateness of aggression to motivate the avoidance of its use (Eisenberg & Fabes, 1992; Frick & Morris, 2004; Pulkkinen, 1996; Terranova, Morris, & Boxer, 2008). Moreover, fear reactivity appears to be a significant predictor of overt bullying after one year, controlling the involvement in bullying during the previous year (Terranova et al., 2008).

Another affective state that we will examine is *sadness*. Some researchers have examined the relationship between victimization and depression. Roland (2002) found that children who were victimized at school had higher scores of depression than those who were not involved in bullying; Mills et al. (2004) and Yabko, Hokoda, and Ulloa (2008) also found a significant association between peer-bullying victimization and depression, both for males and females. However, it remains unclear whether depression is a predictor or an outcome of peer-bullying victimization; in other words, it is unclear whether the children were being victimized because they were exhibiting depressive symptoms or the victimization caused the depression.

In this study, we do not intend to use psychiatric categories; therefore, we will refer to sadness rather than depression. Few studies have investigated the relationship between bullying and the specific aspect of sadness. However, these few studies demonstrate that being bullied is significantly associated with feelings of sadness, loneliness and suicidal ideation. In a large survey, which was conducted in 19 low- and middle-income countries, Fleming and Jacobsen (2009) found in all countries that subjects who experienced victimization reported higher scores of sadness than non-victimized subjects, after controlling for the effects of gender and age.

Few studies have considered two or more emotions simultaneously. Investigating the relationships among sadness, anger, bullying and victimization with Dutch students, Camodeca & Gossens (2005) found that both bullies and victims scored higher on anger and attributed more feelings of anger toward the protagonists of hypothetical stories of bullying compared to other children, even though only victims tended to attribute sadness to the protagonists; these results support the hypothesis that anger is an affective state common to bullying and victimization, whereas sadness is specific for victimization.

Although the relationship between bullying and negative emotions has been widely studied, few studies have evaluated the relationships between bullying and quality of life or positive affects (Flaspohler, Elfstrom, Vanderzee, Sink, & Birchmeier, 2009; Glasø, Vie, Holmdal, & Einarsen, 2011; Lokke et al., 2012) such as the affective state of *serenity*, which we will examine in the present study. These studies suggest that students who bully and/or are bullied experience reduced life satisfaction and support from peers and teachers compared to “bystanders” (children who are neither victims nor perpetrators of bullying) and found that positive affect was a partial mediator between exposure to work bullying and job satisfaction or musculoskeletal complaints. These results are consistent with the literature regarding stress

and emotions (Lazarus, 1999) and emotions and health (Folkman&Moskowitz, 2000) and suggest that negative emotions play an important role in the development of a variety of physiological diseases; these studies also suggest that reduced levels of positive emotions also influence victims' health.

Aims and Hypotheses

On the basis of the findings reported in the literature, it is plausible to hypothesize that personal values and exposure to community and interparental violence affect involvement in school bullying and the nature of emotional experience in adolescence. It is also plausible to hypothesize that bullying and being bullied should be associated with positive or negative emotional states. Moreover, we hypothesize that bullying and being bullied have roles in mediating the relationship between values and emotional states and between exposure to violence and emotional states. The hypothesized pattern of relationships is depicted in fig.1.

In line with the theory, the following hypotheses will be tested:

- i) self-transcendence values negatively predict bullying because people who give priority to these values attribute importance to the well-being of others and so tend to not harm them. Moreover, we hypothesize that self-transcendence values, being “healthy” values (Bilsky& Schwartz, 1994), are negatively associated with fear, anger and sadness, and positively associated with serenity;
- ii) self-enhancement values positively affect bullying because youth who attribute importance to these values attempt to obtain power over people and resources. We also hypothesize that self-enhancement values negatively contribute to being a victim of bullying, consistent with the study by Sijtsema et al. (2009). Moreover, we hypothesize that self-enhancement values have a negative impact on emotional well-being (Bilsky& Schwartz, 1994) and therefore, they are positively associated with fear, sadness and anger, and negatively associated with serenity;
- iii) exposure to interparental violence is positively associated with involvement in school bullying, both as a victim and as a bully, and with negative emotional experiences; it is also negatively associated with serenity because children exposed to domestic violence experience higher levels of personal distress, lower levels of social competence and, as a consequence, they are at greater risk for externalizing and emotional problems;
- iv) exposure to community violence predicts involvement in school bullying both as a victim and as a bully, and is positively associated with negative emotional experiences and negatively associated with serenity, through the same mechanisms that we have hypothesized regarding the role of exposure to interparental violence on bullying and affective states;
- v) bullying others is hypothesized to have a direct and positive influence on the affective state of anger (because aggressive behavior is generally linked to feelings of anger), a negative influence on fear (because low levels of fear reactivity put youth at risk for aggression), and a negative influence on serenity (because bullying experience reduces life satisfaction and support from peers and teachers);

- vi) being bullied is hypothesized to have a direct association with emotional states; victims will experience anger in reaction to being bullied, fear because they are not able to defend themselves against the bully attacks, and sadness because they are frustrated at not able to modify their status. Moreover, being bullied reduces life satisfaction and, consequently, feelings of serenity;
- vii) involvement in school bullying is associated to different affective states, mediating the relations between values, family context, community context and emotions, and increasing, in this way, the risk of mental health problems.

In the study, we will control the pattern of hypothesized influences for gender and age.

Figure 1. Conceptual Path Model for the Relationship between Personal values, Exposure to interparental violence, Exposure to community violence, Bullying and Emotions.

METHOD

Participants

This study was carried out in Campania Region, a large and populated area in the south of Italy, the most important city of which is Naples. The research was commissioned by the Regional Department of Education and conducted by the Regional Observatory on Bullying and the Department of Psychology of the Second University of Naples to investigate the

phenomenon of bullying within schools. The funding agencies had no influence over the choice of research tools and procedures used.

The study was performed in the main five cities of the region (Naples, Avellino, Caserta, Benevento, and Salerno). The different population sizes (higher in Naples than in the other cities) were taken into account. Regarding the socio-economic composition of the studied population, ISTAT (National Institute for Statistics) 2008 indices were used, considering the average level of education and income of the population in relation to the area of residence. The sample comprised 3,546 subjects (1,685 males and 1,861 females) aged between 11 and 18 years, who were middle and high school students from 34 schools and 206 classrooms. In each school, all 7th, 10th and 13th grade classes were selected for inclusion in the study. Ninety-two adolescents refused to participate, and 57 questionnaires were incomplete. The final sample thus consisted of 3,397 adolescents (1,591 males and 1,806 females), of whom 1,275 were enrolled in the second year of middle school (equivalent to 7th grade; mean age=12.39, sd=.74), 1,021 were enrolled in the second year of high school (equivalent to 10th grade; mean age=15.58, sd=.78) and 1,101 were enrolled in the fifth year of high school (equivalent to 13th grade; mean age=18.27, sd=.99). The sample was relatively well distributed in terms of socio-economic status, though somewhat skewed toward lower levels. Approximately 40% of the fathers and mothers had a low level of education (middle school diploma or less), 37% had a high school diploma and approximately 23% had a university degree.

Measures

Values. To measure values, adolescents completed four sub-dimensions of a reduced version of the Portrait Value Questionnaire (PVQ; Schwartz, Melech, Lehmann, Burgess, Harris, & Owens, 2001), a self-reporting scale based on Shalom Schwarz's theory and validated in Italy by Capanna, Vecchione, and Schwartz (2005); these sub-dimensions are benevolence, universalism, achievement and power. The four values have been further categorized into two higher-order dimensions: self-transcendence (benevolence and universalism) and self-enhancement (achievement and power). The PVQ includes verbal portraits of different people who describe a person's goals, aspirations or wishes that point implicitly to the importance of a value. For each portrait, respondents answer the question "How much like you is this person?" Typical items include the following: "It is very important to him to help people around him. He wants to care for their well-being" (self-transcendence); "He likes to be in charge and tell others what to do. He wants people to do what he says" (self-enhancement). All items were scored on a six-point Likert scale from 1 = *not at all like me* to 6 = *very much like me*. The instrument demonstrated adequate reliability [benevolence (2 items): Cronbach's alpha = .68; universalism (3 items): Cronbach's alpha = .67; achievement (2 items): Cronbach's alpha = .70; power (2 items): Cronbach's alpha = .68].

Exposure to interparental violence. Youths' exposure to interparental violence was measured with a modified version of the Conflict Tactic Scales (CTS; Straus, 1979) adapted for Italian youngsters by Baldry (2003). The used scale consists of 4 items that measure various levels of violence between parents. The types of violence that we measured are: verbal (name calling), physical (hitting and throwing objects at the partner), and emotional (threatening), plus a general question measuring "harm doing" (e.g.: "Has your father/mother ever hit your mother/father in some ways?"; "Has your father/mother ever threatened your

mother/father?"; Cronbach's $\alpha = .79$). We asked subjects to indicate the frequency with which they had been exposed to the situations in question over the last year using a 5-point scale (1 = *never*; 5 = *very often*).

Exposure to community violence. Exposure to violence was measured by a questionnaire (Bacchini et al., 2011) on "exposure to violence in the community". The questionnaire was derived from Schwartz and Proctor's Community Experience Questionnaire (Schwartz & Proctor, 2000) and adapted to local conditions. The questionnaire contains two subscales. The first subscale includes 5 items assessing exposure to community violence as a victim (Cronbach's $\alpha = .65$) including, for example the following questions: "How many times have you been the victim of theft (robbery, bag-snatching)?" "How many times have you been attacked or threatened?". The second subscale includes 5 items assessing exposure to community violence as a witness (Cronbach's $\alpha = .80$) including, for example, the following questions: "How many times have you witnessed thefts (robbery, bag-snatching)?" "How many times have you seen attacks on or threats against other people?". For each item, we used a 5-point scale (1 = *never* to 5 = *very often*) to elicit information on the frequency with which the participant had been exposed to the situation in question over the last year. Participants were reminded to report only serious, real-life events from their neighborhoods and communities rather than events that they had read about or had seen on television or in movies.

Bully-victim questionnaire. To measure the frequency of bullying, we adapted the classical bully-victim questionnaire, originally proposed by Olweus (1986, 1996), modified by Whitney and Smith (1993) and adapted for Italy by Genta, Menesini, Fonzi, Costabile, and Smith (1996). Before administering the questionnaire, we provided students with a definition of bullying. The definition was centered on three key concepts: the imbalance of power between the victim and the perpetrator, the intention to harm the victim and the different forms that bullying can take. Subsequently, a series of 8 questions on bullying were given. Bullying questions included questions regarding insults, blows, threats, isolation inside school, isolation outside school, defamation, theft, and teasing. For each question, subjects indicated the frequency with which they had experienced being bullied or had bullied others from the beginning of the school year on a 5-point scale (*never involved, only once or twice, 2 or 3 times a month, about once a week, several times a week*). Lastly, two scales including all items were constructed for being a victim (Cronbach's $\alpha = .75$) and being a bully (Cronbach's $\alpha = .77$).

Emotions. Emotional experiences were measured using a modified version of the Positive and Negative Affect Schedule (PANAS; Watson et al., 1988). For this study, we used negative affect scales (fear, anger, and sadness) and a positive affective state, serenity. The respondents were asked to what extent they generally felt those emotions during the previous 2 weeks. The response categories were: *not at all/very slightly, a little, moderately, quite a bit, and extremely*.

Procedure

The study was realized in the spring of 2010. The questionnaires were administered in the classroom by previously trained psychologists who had not previously met the students. During the administration of the questionnaires, which took place over a period of 1 month, teachers were not present in the classroom. All questionnaires were anonymous. All the parents of the students involved signed an informed consent form that specified the goals of the study. At the

end of the study, the local government received a copy of the research report. The main findings were presented to 15 meetings of students, parents and teachers.

RESULTS

Table 1 shows means and standard deviations of personal values, exposure to interparental violence, exposure to community violence, bullying and emotions. Hypothesized effects of gender and grade class level were evaluated using a 2 x 3 (gender [males, females] x grade class [7th grade, 10th grade, 13th grade]) multivariate analysis of variance (MANOVA). In the analysis, gender and grade level were considered as design variables, and all other variables were considered dependent variables. The results revealed a significant effect of gender (Wilks' λ = .82; F = 55.04; df = 13,3379; p < .0001; η^2 = .17), grade class (Wilks' λ = .85; F = 22.14; df = 26,6758; p < .0001; η^2 = .08), and interaction gender*grade class (Wilks' λ = .98; F = 2.32; df = 26,6758; p < .0001; η^2 = .01).

In particular, the post hoc analyses showed that males had higher scores for achievement, power, being a witness and a victim of community violence and being a bully at school, whereas females had higher scores for benevolence, universalism, exposure to interparental violence, fear, anger and sadness. With increasing age (grade class), personal values, exposure to community violence, fear, anger and sadness increased, while being a victim and serenity decreased. The interaction between gender and grade class showed that, with increasing age, exposure to community violence as a witness increased in males but not in females (F = 9.44; p < .001; η^2 = .01) and that serenity decreased in females but not in males (F = 7.19; p < .001; η^2 = .01).

Means, standard deviations and linear correlation coefficients among variables are listed in Table 2. The analysis revealed many significant relationships. In particular, values were significantly correlated with being a bully but not with being a victim, and exposure to interparental violence and exposure to community violence were significantly and positively correlated with being a victim and being a bully. Furthermore, being a victim was significantly correlated with all emotions, whereas being a bully was significantly correlated with anger, sadness and serenity but not with fear.

To test the hypotheses regarding the relationships among values, exposure to interparental violence, exposure to community violence, bullying and emotions, we used gender and age multi-group Structural Equation Modeling (SEM) analyses (LISREL 8, Joreskog & Sorbom, 1996).

The model included one observed exogenous variable (exposure to interparental violence), three latent exogenous variables (self-transcendence, self-enhancement, exposure to community violence), and six observed endogenous variables (being a victim, being a bully, fear, anger, sadness and serenity). Self-transcendence was measured in terms of benevolence and universalism, self-enhancement was measured in terms of achievement and power, and exposure to community violence was measured in terms of exposure to violence as a victim and/or as a witness. Indices of fit and path coefficients were examined using maximum-likelihood estimates.

Table 1. Mean and Standard Deviations for Measures of Personal values, Exposure to interparental violence, Exposure to community violence, Bullying and Emotions by gender and grade class

	Males (1591)		Females (1806)				7th Grade (1275)		10th Grade (1021)		13th Grade (1101)

We used a number of different indicators to assess the fit of the model. A χ^2 analysis was used to test the fit between the matrix of observations and the matrix generated by the model. However, in large samples, this statistic is strongly influenced by small differences between distributions, which may bias statistical conclusions regarding the fit of the model (Bollen, 1989). To avoid this difficulty, we used other indices, such as the Comparative Fit Index (CFI) and the Non-Normed Fit Index (NNFI). The possible values of these indices vary between 0 and 1 and, in general, values higher than .90 represent a satisfactory fit (Bentler, 1990). We also used the Root Mean Square Error of Approximation (RMSEA), which measures the difference between estimated and observed parameter values. For this measure, values between 0 and .05 indicate an excellent fit, and values between .05 and .08 indicate an acceptable fit (Brown & Cudeck, 1993). To investigate whether we should use identical models for males and females and for different age groups, we applied the multi-sample procedure suggested by Joreskog and Sorbom (1996).

In the first model, the relationships between the variables were examined simultaneously for male and female subjects. With configural invariance (the model is similar for both groups, but all paths are allowed to vary), the fit for this model was: $\chi^2(54)$ 405.91, $p < .05$; NNFI=.88; CFI=.96; RMSEA=.06 (.06-.07). Next, we set identical structural paths for males and females and, with scalar invariance (all paths are constrained to be the same for both groups), the fit for this model was: $\chi^2(86)$ 482.28, $p < .05$; NNFI=.92; CFI=.95; RMSEA=.05 (.05-.06). An examination of the modification indices suggested that we could improve the fit of the model by estimating five structural paths separately for males and females (see table 4). After this refinement, the model fitted the data well: $\chi^2(81)$ 443.46, $p < .05$; NNFI=.92; CFI=.96; RMSEA=.05(.05-.06). The χ^2 analysis for the model with scalar invariance was significantly poorer than that for the baseline model (configural invariance). Therefore, we chose the final model (partial scalar invariance) because it shows better fit, a non-significant χ^2 statistic and is more parsimonious. The standardized path coefficients for the final model are presented in table 4. Table 3 shows indices of fit and the $\Delta\chi^2$ statistic.

The results showed that, in both genders, self-transcendence was negatively associated with being a bully but not with being a victim, self-enhancement was positively associated with being a bully but not with being a victim, exposure to interparental violence and exposure to community violence were positively associated with being a bully and being a victim.

Additionally, being a victim was positively associated with fear, anger, and sadness, and negatively associated with serenity, whereas being a bully was positively associated only with anger. Furthermore, self-transcendence, exposure to interparental violence and exposure to community violence were directly associated with all emotions, whereas self-enhancement was directly associated only with anger.

Analyses of indirect effects indicated statistically significant mediation between exposure to interparental violence and fear (males and females: $\beta = .01$, $z = 4.88$, $p < .001$), anger (males and females: $\beta = .01$, $z = 3.55$, $p < .001$), and sadness (males: $\beta = .01$, $z = 4.30$, $p < .001$; females: $\beta = .02$, $z = 4.85$, $p < .001$), and between exposure to community violence and fear (males: $\beta = .04$, $z = 5.50$, $p < .001$; females: $\beta = .02$, $z = 4.97$, $p < .001$), anger (males: $\beta = .02$, $z = 3.74$, $p < .001$; females: $\beta = .02$, $z = 3.54$, $p < .001$), and sadness (males: $\beta = .04$, $z = 4.71$, $p < .001$; females: $\beta = .04$, $z = 5.38$, $p < .001$) via being a victim, and between self-transcendence and anger (males and females: $\beta = -.02$, $z = -4.99$, $p < .001$), self-enhancement and anger (males and females: $\beta = .01$, $z = 4.84$, $p < .001$), exposure to interparental violence and anger (males: $\beta = .02$, $z = 4.61$, $p < .001$; females: $\beta = .01$,

$z=4.03$, $p<.001$) and exposure to community violence and anger (males and females: $\beta=.03$, $z=5.71$, $p<.001$) via being a bully.

Overall, the model explains a reasonable percentage of the variance for being a victim (10% for males and 9% for females), being a bully (11% for males and 19% for females), fear (8% for males and 5% for females), anger (11% for males and 11% for females), sadness (12% for males and 12% for females), and serenity (10% for males and 9% for females).

In the second model, the relationships between the variables were examined simultaneously for 7th grade, 10th grade, and 13th grade subjects. With configural invariance, the fit for this model was: $\chi^2(81)$ 477.09, $p<.05$; NNFI=.87; CFI=.95; RMSEA=.07 (.06-.07). Next, we set identical structural paths for 7th grade, 10th grade, and 13th grade subjects, and with scalar invariance, the fit for this model was: $\chi^2(145)$ 652.24, $p<.05$; NNFI=.91; CFI=.94; RMSEA=.05 (.05-.06). An examination of the modification indices suggested that we could improve the fit of the model by estimating eight structural paths separately for 7th grade, 10th grade, and 13th grade subjects (see table 6). After this refinement, the model fitted the data well: $\chi^2(136)$ 544.70, $p<.05$; NNFI=.92; CFI=.95; RMSEA=.05(.05-.06). The χ^2 analysis for the model with scalar invariance was significantly poorer than that for the baseline model (configural invariance). Therefore, we chose the final model (partial scalar invariance) because it shows better fit, a non-significant χ^2 statistic and is more parsimonious. The standardized path coefficients for the final model are presented in table 6. Table 5 lists indices of fit and the $\Delta\chi^2$ statistic.

Table 3. Gender multi-group models fit indices

DISCUSSION

The goal of this study was to analyze the relationship between exposure to violence, personal values, emotional experience and involvement in school bullying, while comparing gender and age within adolescence. Our hypotheses were that personal values and exposure to interparental and community violence affected involvement in school bullying and emotional experience and that school bullying directly affected emotional experience and indirectly affected the relationship between personal values, exposure to violence and emotional experience. This pattern of relationships was tested using a system of structural equations that partially confirmed the plausibility of the model.

Gender and age also play a significant role when compared with the mean values of each variable in the model, but they have a very modest effect when we analyzed the model of the relationships among the variables.

Table 6. Relations between Personal values, Exposure to interparental violence, Exposure to community violence, Bullying and Emotions. Standardized path coefficients. First values refer to 7th Grade class group, second values refer to 10th Grade class group, third values refer to 13th Grade class group

	Benevolence	Universalism	Achievement	Power	Victim	Witness	Being a victim	Being a Bully	Fear	Anger	Sadness	Serenity

Note: † Indicates a significant difference with regard to age group. Self transcendence was associated with being a victim and with serenity more strongly in 7th Grade group; Exposure to interparental violence was associated with being a victim more strongly in 7th and 13th Grade group, and with being a bully more strongly in 10th and 13th Grade group; Exposure to community violence was associated with being a victim more strongly in 7th Grade group and with being a bully more strongly in 10th and 13th Grade group; Being a victim was associated with serenity more strongly in 10th Grade group; Being a bully was associated with anger more strongly in 7th Grade group. *p<.01 **p<.001

The main advantage of our model is that it makes possible to simultaneously consider a range of different variables that previous studies have generally considered only in a pairwise manner.

Gender and Age Differences

Regarding specific results, the first issue we discuss is the role of gender and age.

Gender differences are significant for all the variables considered, except for being a victim and serenity. Regarding values, females attached a higher priority to self-transcendence whereas males attributed greater importance to self-enhancement. These findings confirm the results of cross-cultural studies (Schwartz & Rubel, 2005) showing that women attribute more importance to benevolence and universalism whereas men attach higher priority to power and achievement.

Female scores for interparental violence were higher than male scores. This finding could be because daughters spend more time at home or, more probably, as females are more sensitive to familial violence and are more involved in family dynamics.

Conversely, males were more exposed than females to community violence both as a witness and as a victim. There is some evidence that boys, who spend more time away from their familiar context, are more likely to be victims and witnesses of community violence than girls, excluding incidents involving sexual violence (Bell & Jenkins, 1993).

We also found that males reported higher rates of bullying than did females (Espelage et al., 2000; Olweus, 1993). However, it is possible that the rates of bullying of females are slightly underestimated. Many studies have confirmed differences between boys and girls in their respective forms of aggression. Although physical and verbal aggression appears more common among boys, aggression through exclusion, gossip or other relational and indirect forms seems to be the preferred form among girls (Björkqvist, Lagerspetz, & Kaukiainen, 1992; Crick & Grotpeter, 1995; Galen & Underwood, 1997; Salmivalli & Kaukiainen, 2004).

Finally, we found gender differences for negative emotional experiences. Our findings are consistent with a large body of literature according to which women are more emotionally vulnerable than men during adolescence, and more inclined to experience negative and dysphoric feelings (Fleming & Offord, 1990).

As regard the role of *age*, the results revealed that the rates of values, exposure to community violence, fear, anger and sadness were higher for the older age groups, whereas the rates of being a victim and serenity were higher for the younger age groups.

Regarding personal values, both the mean ratings for self-enhancement and self-transcendence were higher for the older groups. It is possible to hypothesize that value priorities become more defined, clear and crystallized as the individual matures; in this way, the mean rates of all values become higher in the transition from early to late adolescence because the commitment to a specific set of value priorities increases during this developmental period (Knafo & Schwartz, 2004).

Additionally, we found that older youths reported higher rates of exposure to community violence than younger youths, most likely because the time spent out of home and in the neighborhood increases during this age; therefore, these youths become more likely to be a witness or victim of community violence (Dodge, Coie, & Linam, 2006).

Moreover, our results showed that, in accordance with the literature (Olweus, 1993), being a victim at school decreased with time. This result could be due to various causes. Some victims can leave school because they fail to integrate into their peer group or they can acquire a new social competence and become able to respond to the prevarications with appropriate strategies.

Finally, our findings show that the negative emotional states (anger, fear and sadness) increase while the positive emotional state (serenity) decreases. These findings are consistent with a vision of adolescence as an age characterized by emotional instability (Cooper, Wood, Orcutt, & Albino, 2003).

However, it is necessary to specify that the gender and age differences found in our study are limited to the differences among variable means and do not affect the relationships among the variables in the structural equation model.

Personal Values, School Bullying and Emotional States

The findings are consistent with the hypothesis that self-transcendence values negatively predict bullying but not victimization. This result is consistent with the literature, according to which values oriented toward the welfare of others appear to act as protective factors against bullying (Menesini et al., 2011) and violent behavior (Knafo, Daniel, & Khouri-Kassabri, 2008).

People who prioritize universalism and benevolence values attribute importance to equality among all human beings, promote respect and tolerance towards others, have high levels of empathy (Balliet, Joireman, Daniels, & George-Falvy, 2008) and tend to act in a prosocial way (Caprara & Steca, 2007).

Findings concerning the relationship between self-transcendence values and emotions are contrasting. Self-transcendence had a negative indirect effect on anger via being a bully and a positive direct effect on serenity. On the basis of these findings, it is possible to hypothesize that these types of personal values could have a protective role with respect to emotional well-being under certain conditions. However, it is necessary to specify that the direct effects of self-transcendence values on anger, sadness and fear are significant and positive, different from our hypotheses. This result could be due to many different causes. One hypothesis is that people who attach importance to self-transcendence values – being very empathic (Balliet et al., 2008) and characterized by high feelings of concern for others (Nelissen, Dijkers & de Vries, 2007) – tend to respond to external events with a strong emotional reaction.

Regarding self-enhancement, the results are partially in accordance with our hypothesis, showing that power and achievement are positively associated with being a bully but not associated with being a victim. The role of self-enhancement as a risk factor for externalizing behavior is supported by the literature (Knafo, 2003; Sijtsema et al., 2009). People who attach importance to self-enhancement want to gain power over people and resources and to reach high social status inside the group, even at the expense of others; they tend to focus on their own personal interests without considering the needs of others.

Regarding self-enhancement, the results showed an indirect effect on anger via being a bully, even if, in this case, the association is positive. A positive association between the power value and anger was also found by Nelissen, Dijkers and De Vries (2007). It therefore appears that attributing importance to power and achievement could represent a risk factor also for the emotional well-being of individuals. It is possible to hypothesize that people who focus on their

personal interests react with high levels of anger when someone or something obstructs the attainment of their goals.

Interparental Violence, School Bullying and Emotional States

Regarding the role of interparental violence, the results are in accordance with our hypothesis. We found that interparental violence was positively associated with both being a bully and being a victim at school (Baldry, 2003; Bauer et al., 2006).

It is plausible to hypothesize that children learn appropriate and inappropriate interactions by observing significant others in their environments. They learn to bully others through observation and, conversely, less bullying behavior is associated with observing positive adult role-modeling (Espelage et al., 2000). Moreover, by observing violence in the family, children may learn to accept bullying and aggression as legitimate ways to interact with their peers.

Meanwhile, interparental violence is linked to victimization. Perhaps the different reactions (becoming a victim or a bully) are linked to personal variables such as emotional regulation abilities or coping skills.

Moreover, the results showed that exposure to interparental violence had a positive direct effect on all emotions, a positive indirect effect on all emotions via being a victim, and a positive indirect effect on anger via being a bully. It therefore appears that, in families where there are higher levels of violence, the parents are most likely unable to take care of their children; therefore, the children internalize an unsupportive model, are consequently at greater risk for emotional problems and their well-being level decreases (Hetherington & Stanley-Hagan, 2002).

Community Violence, School Bullying and Emotional States

Regarding the role of exposure to community violence, the results are consistent with the literature and with our hypothesis. Specifically, we found that exposure to community violence was positively associated with being a bully and being a victim (Andershed et al., 2001; Bacchini et al., 2009; Espelage et al., 2000; Khoury-Kassabri et al., 2004; Nansel, et al. 2003; Schwartz & Proctor, 2000; Swearer & Doll, 2001; WienkeTotura et al., 2009). As schools are established in neighborhoods, it is undeniable that the schools share beliefs, personal values, attitudes to violence, and power hierarchies with the neighborhood and that an unsafe neighborhood environment can influence bullying behaviors in many ways. Where abuse is common in the environment, violent behavior becomes a normal feature of school life (Phillips, 2003), and bullying is seen – by bullies and victims alike – as a normal part of everyday living (Batchelor, Burman & Brown, 2001; Percy-Smith & Matthews, 2001). Regarding the effect of exposure to violence on being a bully, it is possible to hypothesize that youths who frequently observe aggressive models in their living context adopt these types of behaviors as their own and develop beliefs that aggression is an effective way of solving social issues and reaching their goals (Bandura, 1986). As for victims, one hypothesis is that exposure to community violence can reduce emotional regulation abilities and, in turn, this impaired emotional regulation puts them at greater risk for becoming a victim of bullying in the school context (Schwartz & Proctor, 2000).

Moreover, the results showed that exposure to community violence had a positive direct effect on all emotions, an indirect positive effect on all emotions via being a victim, and an indirect positive effect on anger via being a bully. It therefore appears, in accordance to the literature, that exposure to community violence is also a risk factor for the emotional well-being of individuals. In fact, youths exposed to community violence had higher levels of personal distress and (most likely as a consequence) are at greater risk for emotional problems (Bacchini et al., 2011; Gorman-Smith et al., 2004; Ho, 2008).

School Bullying and Emotional States

The last issue we wish to discuss is the direct link between bullying and emotional experience. The results are partially in accordance with the literature and with our hypothesis. Specifically, we found that being a bully was positively associated with the affective state of anger but not with other negative emotional states (as fear and sadness); being a victim was positively associated with all the negative affective states that we explored and negatively associated with serenity (Champion, 2009; Flaspohler et al., 2009; Glaso et al., 2011; Lokke et al., 2012; Roland, 2002; Sigfusdottir et al., 2010; Terranova et al., 2008; Yabko et al., 2008). According to the SIP model (Crick & Dodge, 1994), youths who show high levels of externalizing problems develop more hostile attributions in ambiguous situations; similarly bullies can attack others because they feel threatened and perceive others as unsupportive or hostile, thereby increasing their anger levels. Regarding the victims, we observed a decrease in well-being and an increase in negative emotions in our data; this finding might be due to the condition of social isolation that victims experience in the school context. The literature supports the evidence that victims are frequently rejected by other peers (Bacchini, Affuso, & Trotta, 2008; Cerezo & Ato, 2005), and most likely the lack of emotional and social support, and the impossibility to share the experiences with others can reduce personal well-being and amplify negative affective states, especially at this age (Dunn, 2004; Sullivan, 1953).

Limits and Implications of the Study

The findings and conclusions of our study should be interpreted with caution because several factors limit the explanatory power of our data. One limitation of this study is the cross-sectional nature of the data, which provide no insight into the duration of the relationships we observed or their stability over time. Regarding the approach taken in the present research, our aim was to consider emotional experience as an indicator of mental health, even if it is not possible to define the temporal relationship between bullying and emotional experience without longitudinal data. However, because both bullying and emotional experience are almost stable conditions, we can draw some inferences regarding the temporal sequence between them.

A second limitation is our reliance on a single source of information, adolescent self-reporting, which may have led us to overestimate the coherence of our data.

Despite these limitations, we believe that our study makes a useful contribution to the understanding of factors that predict bullying and the effects that bullying have on the emotional lives of adolescents. In particular, we have shown that it is possible to consider

simultaneous relationships among multiple variables in a pre-existent theoretical framework. Future studies will examine the longitudinal stability of these relationships.

The complexity of the links described here implies the need for multilevel interventions in the home, neighborhood, and at school. The aim of such interventions should be to help adolescents to manage and regulate their emotional experiences. To achieve this, the first requirement is to intervene in group dynamics that favor bullying. Bullying is not an intrinsic corollary of the life of groups. Rather, it is the outcome of group processes that can be controlled and modified through appropriate interventions.

Chapter 94

BULLYING/VICTIMIZATION IN PRESCHOOL CHILDREN: INTRAPERSONAL AND CONTEXTUAL FACTORS

Maria Vlachou, Kafenia Botsoglou and Eleni Andreou

University of Thessaly, Department of Special Education and Department
of Primary Education

ABSTRACT

Studies addressing the issue of bullying during the preschool period are still extremely rare. The main aim of the present chapter is to shed some light on the emergence of bullying in preschool children as a social and contextual phenomenon. In relation to this, we carried out an inquiry in order to study verbal, physical and relational bullying, prevalence rates, participant roles undertaken, social status as well as the contextual background of bullying episodes. We also tried to figure out strategies implemented in order to deal with bullying incidences. Psychological correlates associated with bullying such as hostile attribution bias and strategies, empathy and theory of mind were also examined.

167 preschool children (ages 4-6) participated in our research. Research tools were: observation checklists, social status reports, tasks measuring empathy, theory of mind and hostile attribution bias and strategies. According to our findings, bullying in preschool children is a social phenomenon where the whole group of peers in the class is involved. Victimization processes are more closely related to social contextual factors such as peer relations rather than intra-personal factors such as empathy, theory of mind and social information processing. Educational implications and future research directions are highlighted.

INTRODUCTION

Bullying in schools has been identified as a serious and complex worldwide problem associated with negative short- and long-term effects on children's psychosocial adjustment (Ttofi & Farrington, 2008). Most of the research undertaken for studying bullying in schools

has emphasized on middle childhood and adolescence, while there is scarce empirical evidence concerning the manifestation and development of the problem in early childhood years (Alsaker & Valkanover 2001; Monks, Ruiz & Val, 2002; Hanish, Martin, Fabes, Leonard, & Herzog, 2005; Perren & Alsaker 2006). However, the evidence emanating from the limited number of studies available supports the existence of this problem even in such an early developmental phase and addresses its adverse effects on many aspects of children's later life including school avoidance, peer rejection, emotional difficulties, etc. (Kochenderfer & Ladd 1996).

Entering formal preschool education is a crucial developmental step in many children's lives mainly because it is within this context where they participate, for the first time, as members in a stable peer group and well-organized team activities. Consequently, preschool may be the first context beyond the home environment where children's difficulties in social interactions with peers can be primarily detected and assessed by adults and professionals. The early identification and elimination, therefore, of these problems at this young age prevent their escalation in later years and minimize their negative impact on children's social and emotional development while foster their successful adaptation in school. Despite the growing interest in bully/victim problems in school, studies that have addressed this issue in the preschool years are extremely rare. This may be due to methodological constraints posed upon researchers when examining preschool populations (Vlachou, Andreou, Botsoglou & Didaskalou, 2011).

THEORETICAL BACKGROUND

Bullying in Preschool Children – Prevalence Rates

Bullying is defined as an aggressive behavior of intentional 'harmdoing', which is carried out repeatedly and over time within a personal relationship characterized by an imbalance of power (Olweus, 2010). Bullying may take a variety of forms including physical and verbal abuse, social isolation, and/or exclusion. Previous research has shown that children take on central as well as peripheral participant roles. The central roles include: a) bullying others without being victimized, b) bullying others and also being victimized by classmates and c) become the target of others' aggression without being aggressive towards others. Peripheral roles refer to indirect participation in a bullying event. Thus, children may be involved in bullying by assisting the bully (assistants), providing the bully with positive feedback (reinforcers), taking sides with the victim (defenders), or remaining uninvolved and thus silently approving of the bullying (outsiders).

Prior data showed that bullying is a serious problem even in the preschool. In a study conducted with preschool children in Switzerland, results demonstrated that 6% of children were classified as victims, 10% as bully-victims, 11% as bullies, and 47% were not involved in bullying. A 17% of the remaining children could not be categorized according to the researchers' restrictive criteria (Perren & Alsaker, 2006). Using peer nominations, Monks, Smith and Swettenham (2005) found that preschool participants nominated peers for taking the roles of aggressor, victim or defender. Although almost 30% were not assigned to any clear role, a quarter were assigned to the role of aggressor, 22% to the role of victim and 16% to the role of defender.

Preschool Children's Perception of "Bullying/Victimization"

Victimisation refers generally to being the recipient of aggressive acts. Children aged 4 years appear to understand the term "victim". However, they have a different understanding of the term "bullying" from older children, defining it as being aggression in general (Smith, Cowie, Olafsson, & Liefhoghe, 2002) rather than as being a repeated act by a more powerful aggressor. First, it is clear that younger children do not pay so much attention to the limiting characteristics of repetition, imbalance of power and intention as do older children. Madsen (1996) examined age trends in the perception and understanding of bullying, asking participants aged 5 years to adulthood, 'What do you think bullying means?' Very young children used adjectives and direct examples more than older children, but rarely mentioned repetition or the actions being unprovoked. Many pupils felt that the behaviour did not have to be repeated, depending upon the severity of the behaviour and the effect on the victim. Pupils also deemed the adverse effect on the victim to be the essential feature in defining bullying. In this case, a situation could be perceived as bullying by others even if it was not the intention of the perpetrator to bully.

Smith et al. (2002), using a cartoon methodology, reported that younger children (aged 8 years) were more likely to simply distinguish between aggressive and non-aggressive scenarios, whereas older children (aged 14 years) were able to make finer grained distinctions between types of aggression: physical, verbal and social exclusion. Finally, younger children often nominate peers for the roles of aggressor, victim, and defender, they do not so often nominate peers for the more peripheral roles of assistant, reinforcer, or outsider in aggression (Monks et al., 2002).

According to the research conducted by Monks and Smith (2006), most preschool children were able to identify verbal, physical and indirect or relational aggression as bullying when presented with them in cartoon form. Power differences and repetition of actions were not taken account of in this way. Also, in the same study, preschool participants were not reliable to recognize the role of the victim.

In a more recent research, Alsaker and Nagele (2008) interviewed preschool children individually so that the interviewers explained the term bullying by means of four drawings, each depicting a different form of bullying (physical, verbal, property-related, or exclusion). Using photographs of all children in the class, they asked each child to nominate children who bullied others and to indicate the targets of these aggressive behaviors. According to the findings, children knew very well who were the targets of the bullying, when asked in this manner.

Measuring Bullying in Preschool Children

The most common methods for measuring bully/victim problems or related concepts are relevant anonymous questionnaires, and more specifically: 1. self-reports, 2. peer nominations, and 3. teacher reports. In order to complete the questionnaires, the respondents are invited to recall past events and identify central participant roles to themselves or the others undertaken frequently (e.g., once a week) (Olweus, 2010). Sometimes those questionnaires are pitted against one another and some authors have expressed a clear preference for one of the questionnaires, while others have claimed that those questionnaires provide valuable but

incomplete information and that the best thing may be to combine information from both data sources (Berger, 2007). It goes without saying that completing questionnaires requires literacy skills from the part of the respondents. Therefore, using self-reports and peer nominations in preschool populations are not indicated. Researchers have proposed an alternative method of collecting data in early childhood studies. Structured interviews using visualized materials (cartoons, photographs) and age-appropriate questions replace traditional completion of questionnaires (Monks & Smith, 2006).

There are a number of significant drawbacks when using peer nominations and self-reports in young children. First, it is difficult for young children to reliably recall information about bullying episodes (Alsaker & Gutzwiller-Helfenfinger, 2010). Responding to questions depends largely on the way participants perceive their content, and on their ability to recall painful events. Finally, responses to those questionnaires may be prejudiced by a child's reputation, could be characterized by gender stereotypes, and significant information might be omitted according to respondents judgment (Ladd & Profilet, 1996). For example, respondents may exaggerate their experiences or may refuse involvement in bullying episodes (Cook, Williams, Guerra, & Kim, 2010). Bearing all the above in mind there are substantial reasons for being skeptical about using peer-nominations and self reports in preschool populations (Cornell, 2006).

Regarding teacher reports, it has been attested that this is a more reliable method than peer and self-reports when conducting studies with preschool children (Crick, Casas, & Ku, 1999). It has been argued that preschool children are more impulsive and less inhibited than school age children, and therefore engage in victimization procedures even when adult supervisors are not present (Coie, Dodge, & Kupersmidt, 1990; Vlachou, 2011). Preschool teachers are reliable when reporting the victims of bullying episodes but seem to be reluctant when asked to identify the aggressors of the episodes and have difficulties in distinguishing bullying from conflicts (Alsaker, 2003). In relation to peer nominations, self and teacher reports used to measure school bullying there are insufficient data concerning their psychometric properties (Cornell, 2006).

Naturalistic observation constitutes a suitable method for data collection with preschool populations (Craig & Pepler, 1995). Direct observations of playground behaviors tend also to be more objective than peer, teacher, or parent reports (Leff & Lakin, 2005). Observational methods enable researchers to identify behavioral patterns within the naturalistic contexts at the time during which they actually occur, and, thus, the social validity of these systems is often a strength (Hintze, Volpe, & Shapiro, 2002) that adds to external validity (Craig, Pepler, & Atlas, 2000). Despite the time, cost, and potential for observer biases, the focal child approach proposed by Ostrov, Crick, and Keating (2005) constitutes according to its authors an ecologically valid method, has acceptable psychometric properties and therefore consists a more objective source (Ostrov, Crick, & Stauffacher, 2006). Also, during naturalistic observations scholars have the opportunity to record and note down in details data that describe not only central and peripheral roles but also the social and physical context of those episodes (Vlachou, 2011). Although observations are valuable research means, there is little relevant data in relation to victimization processes in preschool children (Ostrov & Keating, 2004).

PHYSICAL ENVIRONMENT AND BULLYING

Children's safety and security at school has become a high priority for institutions and teachers. Emphasis has recently been placed on the impact school physical environment is likely to exercise upon students' behavior, i.e., teacher's supervision and proximity, open versus closed spaces.

Bullying Episodes on the Playground

Many studies have shown that playground areas are typically more conducive to aggressive behavior than the classroom setting (Craig & Pepler 1997). Craig et al. (2000) have, for example, found that aggressive behaviors occurred nearly twice as frequently on the playground as in the classroom while aggressive acts on the playground were longer in duration than that within classrooms. The review of the relevant literature points to some important aspects of playground settings that are likely to affect children's behavior and should be taken into consideration by educators and professionals for promoting children's safety and well-being in schools. These include (a) playground activities available to children for example cooperative versus competitive activities (Pellegrini, Blatchford, Kato, & Baines, 2004), (b) the ratio of playground supervisors to children (Ladd & Price 1993), (c) active supervision (Leff, Power, Costigan & Manz, 2003; Nabors, Leff & Power, 2004), and (d) establishing playground rules (Leff et al. 2003). Despite the availability of the above-mentioned strategies, teachers still encounter difficulties in supervising playgrounds and eliminating children's aggressive interactions effectively within these areas mainly because they cannot always be aware of bullying incidents that occur privately between peers (Cairns & Cairns 2000). Given the distance and noise present on the playground, adults are often unaware of verbal playground aggression that has occurred (Craig & Pepler 1997). Furthermore, because most children know that aggression is prohibited, they may make a point of restricting physical aggression toward peers to the hidden corners of the playground, out of the sight of adult supervisors (Pellegrini, 1990).

Bullying Episodes in the Classroom

Recently, Maxwell (2007) assessed physical environment's impact on and role in children's cognitive and social development and concluded that it is related to measures of competency. Legendre (2003) searching for the environmental features of day-care centers likely to affect toddlers' emotional and stress reactions in group settings found out that the physical and social attributes of preschool settings intervene in the regulation of children's bioemotional reactions. The findings of a recent study investigating the correlation between the physical environment and aggression in the preschool context reveal that certain play areas within classrooms are also associated with physically aggressive behaviour (Adams 2008). Consideration of open versus closed centers also provides some explanation of aggression in children. Open centers include blocks, art, dramatic play, language, cubbies, and the table tops. Closed centers include sand/water table, nature/science, music, language, and the bathroom. A

third type of location within the classroom is the undefined spaces, simply known as other areas. These locations provide some suggestion of anticipated aggression, since the open centers allow for greater creativity and expression of self between children. Undefined and unspecified spaces providing no organization for social skill expectations for children may foster aggressive behavior. On the other hand, closed centers encourage children to explore either independently or enjoy with a peer a more quiet or passive activity (Adams 2008). Locations within the classroom must receive consideration in designing intervention strategies for the reduction or elimination of particular aggressive acts of preschool children. Especially important are the consideration of the overall classroom arrangement and the organization of those areas where their use by children has not been specified, for instance, teacher areas, large open spaces, and walk through pathways leading to other classrooms. Planning and arranging the layout of each common area is essential in ensuring positive social interactions among children (Harms, Clifford & Cryer, 1998).

SOCIO-COGNITIVE CORRELATES

Apart from environmental factors, intra-personal factors, such as socio-cognitive skills, may influence bullying interactions. Social development in children includes the management of several competences that allow people to create and maintain satisfying relationships in their own social context. This relates to a person's ability to comprehend intentions, states of mind, and emotions.

Theory of Mind

Theory of mind was first introduced by Premack and Woodruff (1978) who defined theory of mind as: *"An individual has a theory of mind if he imputes mental states to himself and others. A system of inferences of this kind is properly viewed as a theory because such states are not directly observable, and the system can be used to make predictions about the behavior of others"*(p. 515). Theory of mind skills can be reliably assessed in children 4 years and above (Liu, Wellman, Tardif, & Sabbagh, 2008).

Prior research examining the role of false-belief and perspective taking during preschoolers' socialisation procedures have shown that they correlate with social skills and social competence (Capage & Watson, 2001). Nonetheless, theory of mind functions have not received much attention in regards to school bullying. Sutton, Smith and Swettenham (1999a) brought evidence according to which, in middle school children, bullies received greater scores in theory of mind skills in comparison to same-age schoolmates. In preschool children, data collected through naturalistic observations have indicated that perspective taking and false-belief skills contribute to a significant decrease of physical aggression in boys presenting low language abilities (Werner, Cassidy, & Juliano, 2006). In the same study, however, no link was found in relation to relational aggression. Monks, Smith and Swettenham (2005) showed that preschool children presenting physical and social aggression did not score higher, than their classmates, on tasks measuring false-belief and perspective taking.

Empathy

Empathy has been defined as “*the ability to understand and share another’s emotional state or context*” (Cohen & Strayer, 1996, p. 988). Empathy is a complex construct in which cognitive and affective aspects can be distinguished (Davis, Luce, & Kraus, 1994). The cognitive component refers to skills of recognizing others’ emotions and taking others’ perspectives, whereas the affective component involves sharing others’ feelings (Feshbach & Feshbach, 1982). In the present study, only the cognitive component of empathy was measured. Empathy was chosen as the individual-level variable to be studied because emotional aspects possibly promoting either pro-bullying or anti-bullying behaviors, such as empathic feelings, have received little attention in this field until very recently (Gini, Albiero, Benelli, & Altoè, 2007; Jolliffe & Farrington, 2006). Empathy can be hypothesized to be related to bullying (Jolliffe & Farrington, 2006).

Researchers have indicated a growing link between pre-school children’s understanding of emotions and verbal and physical aggression. Deficits in emotion knowledge have been linked with behavior problems in preschoolers. Investigators also indicate that children who can effectively and accurately interpret and recognize emotions are more successful at avoiding particular forms of peer-related aggression (Gini, 2006). In a study examining the prosocial roles of defender, consoler and mediator it was found that they are positively correlated with emotion understanding in pre-school children. However, the hostile roles of bully, reinforcer and assistant were not significantly correlated with emotion understanding. Preschool children who were attributed either the victim or the outsider roles were less able to understand emotions than other children (Belacchi & Farina, 2010). In a more recent study, the same researchers (Belacchi & Farina, 2012) investigated the affective and cognitive components of empathy in relation to both emotion comprehension and prosocial/hostile behaviors in preschoolers. Regarding the relations of children’s emotion comprehension with both empathy measures and their prosocial/hostile attitudes, the researches found a robust negative relationship of both affective and cognitive empathy with hostile roles and with outsider role, contrary to a positive correlation of only affective empathy with prosocial roles. No relationships emerged between empathy measures and victim role.

Social Information Processing

The social information processing model of children’s social behaviour has been used to describe a number of processes that are involved in children’s interactions and to explain how aggressive children may exhibit deficits in those processing steps. A reformulation of this model by Crick and Dodge (1994) includes six steps: 1. encoding of cues, 2. interpretation of cues, 3. clarification of goals, 4. response access of construction, 5. response decision, and 6. behavioural enactment. Limited work has been done examining social information processing in preschool children and its relation to victimization. Prior data have provided some evidence that social information processing can be assessed in this age group and that the findings from school-age children also apply in preschoolers (Mize & Ladd, 1988; Werner et al., 2006). Specifically, preschool children who display hostile intent attributions, generate higher levels of aggressive responses, and evaluate aggressive responses positively tend to show higher rates of aggression. Mize and Ladd (1988) conducted a study according to which preschool children

displaying physical aggression reported more hostile strategies than the rest of the group. Also, results from a recent study showed that physical aggression is positively correlated with hostile attribution bias (step 2) as well as with hostile strategies including physical violence (step 5). The same finding was not confirmed as regards to relational aggression (O'Neil, 2008).

SOCIAL STATUS

A well-supported research finding is that some bullies show well developed social competencies, and therefore do not match the traditional view of the aggressive child as socially incompetent (Andreou, 2006; Sutton et al., 1999a). These bullies, among other things, are sociable, assertive, good leaders, popular, and well integrated into the peer group (Perren & Alsaker, 2006). They even show intact or superior theory-of mind skills (Gini, 2006; Monks et al., 2005; Sutton et al., 1999a). These competencies may allow them to anticipate others' thoughts and actions and therefore to efficaciously manipulate the group processes underlying the dynamics of bullying. Certainly, not all bullies are considered to be socially competent.

A distinction relevant for separating socially competent bullies from incompetent bullies is that between bullies and bully-victims (or aggressive victims) (Solberg, Olweus, & Endresen, 2007). Even though aggressive behavior and bullying have been found to be connected with rejection by peers (Boulton & Smith, 1994), some bullies are also well-liked or have a controversial status (Sentse, Scholte, Salmivalli, & Voeten, 2007). Recent data confirms the hypothesis that a number of bullies are popular among their peers, belong to wide social networks, are apt at affiliating, have high social status and emotional competence (Roseth & Pellegrini, 2010).

SCOPE OF THE PRESENT STUDY

The main scope of our study is to investigate contextual and intra-personal factors that would account for victimization processes. Both quantitative and qualitative data will be collected, regarding the background of victimization interactions taking place among preschool children. Using naturalistic observations, we will record interactions of peers into the classroom and on the playground, and will investigate the role of three socio-cognitive correlates, namely empathy, theory of mind and hostile attribution bias and strategies in preschool children.

METHOD

Participants

Participants were 167 children (88 girls and 79 boys) recruited from eight preschools classes in Greece. Schools were randomly selected and were located at middle income urban areas. Of the 167 participants, 115 children were 5 to 6 years old and 52 were 4 to 5 years. Participants came from families of Greek, Albanian and/or East Balkan background. Some participants had a mixed nationality background. All participants had already attended school

for at least two years. Some classes of the same school units, and not whole schools, took part in the present research. Children presenting learning difficulties, disabilities or sensory impairments did not participate in the present research. Teachers and children's parents were contacted directly by the researchers and were thoroughly informed on the content of the present investigation. Parents' written consent was obtained before children were asked for their voluntary participation in the research.

Procedure

Naturalistic Observations

A series of naturalistic observations were carried out in order to record bullying episodes. Participants were observed during regularly scheduled free play periods into the classroom, and outdoors on the playground. The work of Ostrov and Keating (2004) revealed that recording observations on paper as they occurred was less disruptive in preschool settings than videotaping interactions. Thus, we developed an observational checklist and relied on written records of live observations for data collection.

In order to carry out naturalistic observations two trained and experienced observers took notes independently one from the other. In the beginning, the observers were introduced to the children and teachers, spending a few days in the classroom to let others adjust to their presence and to memorize the names of study participants. The observers did not generally interact with the children or with teachers. Their presence into the classroom and on the playground became a routine and was largely ignored. Observations were collected during the middle of the school year, so that the children were well acquainted with each other (Laursen and Hartup, 1989). Also, during the second semester, children would have got to know each other well, and have shared many experiences. In all cases, participant's anonymity was ensured. Each participant (focal child) was observed for a total period of forty minutes, 20 minutes into the classroom and 20 minutes on the playground. Those 40 minutes of observations were divided into 4 periods of 10-minute observations. Therefore, each child was observed at 4 different times interacting with his/her peers over the course of a week. The observers remained within earshot of the focal child and did their best to remain unobtrusive. Interactions with children were avoided by appearing to study information on the clipboards the observers carried. The researchers used an observational form that contained the list of categories as follows: central participant roles (victim, bully, bully-victim), forms of bullying (verbal, physical, relational), forms of play (group, joint, solitary play), group bullying, peripheral roles, the reaction of the victim, the bully and the teacher, active adult supervision and location of the episode. For each bullying episode corresponding categories on the observational checklist were checked. We defined an episode as an incidence (occurrence) during which a victimization interaction took place. Coding for all variables except from participants' reactions was made *a priori*. Based on field notes, data concerning the reactions of victims, bullies and teachers were coded and classified into sub-categories (see Appendix for scoring and coding procedure).

Assessment of Socio-Cognitive Correlates

In order to assess socio-cognitive skills, children were informed that they were going to listen to some stories and respond to relevant questions. The researchers reassured the children that their participation was voluntary and anonymous. They were also told that they could quit

anytime they desired. Interview sessions were carried out in a separate, quiet room adjacent to children's classroom and the whole procedure was held in a friendly and pedagogical climate. For the assessment of the socio-cognitive correlates, structured tasks were adapted into Greek and tested for their reliability. More specifically: For the theory of mind skills, 4 tasks were adapted from those used in previous studies. Those tasks examined the ability for perspective taking, and false belief for content, location and appearance reality (as described in Sabbagh, Bowman, Evraire, & Ito, 2009). For the assessment of emotion understanding we used developmentally appropriate means (puppet matched for participant's gender and colourful pictures) in order to elicit common emotions such as happiness, sadness, fear and anger. After a warm-up session, participants were told stories using both puppets and pictures by the researchers. In the end of each story, children were invited to identify the emotion they thought that the hero would feel. The stories were common to children such as feeling happy for winning a contest, or sad for losing a favourite pet. After mentioning the emotion, the participants were invited to point to the corresponding picture depicting the emotion mentioned (Werner et al., 2006). Finally, hostile attribution bias and hostile strategies were assessed by means of narrating short and familiar stories for children (as described in O'Neil, 2008). Using the methodology of Crick, Grotpeter and Bigbee (2002) participants were told 4 stories about physical aggression and 4 stories about relational aggression. Relevant vignettes were also shown for each story. In the end, children were invited to say whether the heroes intended to do harm or not. Also, they were invited to say how they would react in similar situations.

Social Preference

The respondents were asked to nominate the three classmates they liked the most, and the three they liked the least. The peer-nomination sum score of each item was standardized by class in order to examine *social preference* (calculated by subtracting the standardized like-least nomination score from the standardized likemost nomination score) (Caravita, DiBlasio, & Salmivalli, 2009).

RESULTS

A series of data analyses was carried out. First, the frequencies of central participant roles were calculated in relation to the three forms of bullying. Also, we elaborated data in relation to theory of mind, empathy, hostile bias and strategies and social status. Then, we were interested to analyze the background of bullying episodes. In order to get a more detailed insight on bullying episodes background, we were interested to examine the interaction between some of our research variables.

Prevalence of Central Participant Roles

Based on field notes, children were assigned to the role for which they were observed to undertake twice or more. If they were observed to assume more than one role they were assigned to a dual role (bully-victim). Table 1 illustrates the frequencies for the central

participant roles as noted down by the two researchers separately. Also, agreement between the two raters (Cohen's kappa) was calculated for each form of bullying.

Prevalence rates for the central participant roles were calculated. Our results show that of the 167 participants a 12.6% of the children observed were involved in verbal bullying episodes as perpetrator, victim or bully-victim, a 42.6% in physical bullying, and a 28.1% in relational bullying. In addition, Cohen's Kappa outcomes show that agreement between the two raters for the three forms of bullying is significant.

Table1. Central participant roles in preschool children

		Rater 1 N %	Rater 2 N %	Inter-rater Agreement
Verbal bullying	No central role	146 87.4%	146 87.4%	
	Victim	6 3.6%	4 2.4%	
	Bully	11 6.6%	10 6.2%	
	Bully-victim	4 2.4%	7 4.2%	
				K=.87 Sig=.000**
Physical bullying	No central role	96 57.4%	96 57.4%	
	Victim	31 18.6%	32 19.2%	
	Bully	31 18.6%	28 16.8%	
	Bully-victim	9 5.4%	11 6.6%	
				K=.88 Sig=.000**
Relational bullying	No central role	120 71.9%	120 71.9%	
	Victim	18 10.7%	19 11.3%	
	Bully	24 14.4%	20 12%	
	Bully-victim	5 3%	8 4.8%	
				K=.88 Sig=.000**

*p<.05 **p<.001.

Socio-Cognitive Abilities

In order to examine possible differences between participant roles and socio-cognitive abilities, One-way ANOVAs were administrated. Independent factor was each one of the three forms of bullying and dependent factors were the socio-cognitive abilities of empathy, theory of mind, hostile attributions and hostile strategies. One-way ANOVAs failed to demonstrate significant differences between participant roles and theory of mind in verbal ($F=.57$, $\text{sig}=.63$), relational ($F=.25$, $\text{sig}=.85$) and physical bullying ($F=.32$, $\text{sig}=.80$). However, analyses showed significant differences between participant roles and empathy for verbal bullying ($F=2.65$, $\text{sig}=.05$) but not for physical bullying ($F=1.51$, $\text{sig}=.21$) nor for social exclusion ($F=1.67$, $\text{sig}=.174$). Post-hoc analyses indicated that children not assuming central roles in verbal bullying episodes had higher empathy scores in comparison to bullies and victims. Moreover, statistical elaboration showed significant differences between participant roles and hostile attribution bias for relational bullying ($F=2.94$, $\text{sig}=.03$) but not for verbal ($F=1.33$, $\text{sig}=.24$) nor for physical bullying ($F=1.29$, $\text{sig}=.27$). Scheffe post-hoc test indicated that children not

assuming central roles scored higher in hostile attribution bias than the victims of relational bullying. Finally, statistically significant differences were revealed between participant roles and hostile strategies for relational ($F=3.00$, $\text{sig}=.03$) and physical bullying ($F=8.66$, $\text{sig}=.000$) but not for verbal bullying ($F=.49$, $\text{sig}=.68$). Post-hoc analyses showed that perpetrators of relational bullying reported more hostile strategies than children not assuming central roles. Also, perpetrators of physical bullying episodes reported more hostile strategies than both the victims and the children not assuming central roles.

Social Status

In order to examine the interaction between social status and participant roles, χ^2 test was administrated. Results showed that there is no significant relation between social status and verbal ($\chi^2=7.74$, $\text{sig}=.25$) or relational bullying ($\chi^2=4.53$, $\text{sig}=.60$), but that there is a significant relationship for physical bullying ($\chi^2=17.13$, $\text{sig}=.009$). More specifically, children not assuming central roles in physical bullying episodes belonged to the average peer group whereas perpetrators came from the rejected group. As regards to group bullying, χ^2 revealed that ring-leader bullies are more probable to come from the group of popular peers ($\chi^2=6.64$, $\text{sig}=.03$).

Analyses of Bullying Episodes' Background

At a third phase, data collected through field note-taking were elaborated. Table 2 illustrates the frequencies for aspects related to social features and physical environment of a total of 158 victimization episodes recorded by the two researchers separately. Also, agreement between the two raters (Cohen's kappa) was computed for each category separately.

According to our analyses bullying episodes were more frequently observed during joint play activities (58.2%) rather than group or solitary play. Group bullying was observed in preschool children at a rate of approximately 27%. In addition, we analyzed peripheral roles children undertook during bullying attacks. Our results showed that, almost, eight out of ten episodes observed occurred in the presence of classmates.

Classmates were present at a percentage of approximately 79% of the episodes observed; the majority were passive observers whereas an almost 27% were bully's supporters. Only, 8.9% of the children observed acted as the victim's defender. Outcomes concerning victim's reactions revealed that they behaved in a passive way and at a lower frequency sought help from the teacher. In relation to perpetrators, our analyses showed that either they reacted aggressively or stopped any interaction once their attack came to a successful end. Although in half of the incidences recorded the teacher was physically absent, the times he/she was present, he/she intervened in an active and effective way. According to our analyses, the bullying episodes took place more frequently when adult supervision was not active. In regards to space, results showed that the bullying episodes were more frequent into the preschool classroom (53.8%) rather than on the playground (46.2%).

Table 2. Categories for bullying episodes

Category		Rater 1 N %	Rater 2 N %	Inter-rater Agreement
Play	Group play	64 40.5%	64 40.5%	
	Joint activities	92 58.2%	92 58.2%	
	Solitary	2 1.3%	2 1.3%

	Classroom specified	51 32.3%	51 32.3%	
	Playground non-specified	44 27.8%	42 26.6%	
	Playground specified	29 18.4%	31 19.6%	
				K=.983 Sig=.000**

Interaction between Aspects Related to Bullying Episodes

In order to examine the interaction between categories of episodes recorded, cross-tabulations using χ^2 test of independence were computed. For χ^2 tests only the measurements collected from Rater 1 was used. First, our χ^2 analyses show that group bullying is not related to perpetrators' gender ($\chi^2=1.80$, $p=.18$). Also, we were interested to obtain a closer insight between group-bullying and socio-cognitive factors. Therefore, we conducted a series of t-tests between group bullying and empathy, theory of mind, hostile attributions and hostile strategies of perpetrators. Results showed no main effect between group bullying and empathy ($t=-.91$, $\text{sig}=.36$), theory of mind ($t=1.65$, $\text{sig}=.09$), hostile attributions ($t=-.66$, $\text{sig}=.51$) and hostile strategies ($t=-1.72$, $\text{sig}=.08$).

Consequently, we administrated χ^2 tests which showed that peripheral roles are related to the reactions of both victims ($\chi^2 = 44.34$, $p<.000^{**}$) and bullies ($\chi^2 = 41.56$, $p<.000^{**}$). We adjusted p values for multiple comparisons using the Bonferonni method in order to find out on which terms this relationship is significant. Thus, we found that when observers or assistants were present then the bully tended to augment aggressiveness whereas when the defender of the victim intervened then the bully tended to quit. Lastly, when reinforcers were present then the victim tended to react in a social manner. Also, active adult supervision is related to the reactions of both the bully ($\chi^2 = 10.32$, $p<.016^*$) and the victim ($\chi^2= 10.51$, $p<.015^*$). Using multiple comparisons we found that when an aggressive act ended, victims tended to seek help from the supervisor and bullies tended to stop it immediately. In contrast, when a supervisor was not actively supervising the victim's reaction was passive while the bully tended to insist on behaving aggressively. In relation to active adult supervision, we were interested to examine its interaction with indoor/outdoor space. Analyses revealed that these are two related variables ($\chi^2 = 16.509$, $p<.001^{**1}$). Multiple comparisons showed that when bullying episodes occurred into the classroom, supervision was more frequently active whereas on the playground supervision was less active. In order to get a more detailed insight into the teacher's role, we computed the interaction between teacher's reactions and space ($\chi^2 = 24.25$, $p<.004^*$). Bonferonni method revealed that teachers tend to do nothing when a bullying episode occurs in the non-specified locations on the playground, and this difference is greater compared to the specified places into the classroom. Significant interaction was also revealed between playful activities and the physical environment ($\chi^2 = 56.65$, $p<.000^{**}$). Post-hoc analyses indicated that during joint activities bullying acts are more probable to occur in non-specified spaces into the classroom (and its close surroundings i.e., toilets, corridors), whereas during group activities in the specified areas of both the classroom and the playground. Finally, χ^2 analyses indicated a significant interaction between peripheral roles and specified/non-specified locations ($\chi^2 = 41.45$, $p<.000^{**}$). Multiple comparisons showed that bullying episodes occurred more frequently in interior non-specified places (classroom/corridors/toilets) when peers were not present. Whereas in the specified locations of the classroom and on the playground (both in specified and non-specified areas), peers were present during bullying episodes.

¹ * The Chi-square statistic is significant ≥ 0.05 level. ** The Chi-square statistic is significant ≥ 0.01 level.

DISCUSSION

Our findings indicate that victimization interactions emerge during the preschool years and that participant roles, both central and peripheral, become distinct. The mean prevalence rates including all three forms of bullying were: 10.97% of participants observed to demonstrate the role of the victim, 12.43% the role of the bully, 4.4% the role of the bully-victim. In line with previous studies, we found that physical bullying was more frequently observed in preschool children compared to verbal or relational bullying (Björkqvist, Österman and Kaukiainen, 1992; Björkqvist, Österman and Lagerspetz, 1994).

As regards to results on socio-cognitive factors our analyses indicated that perspective taking and false-belief do not influence participant roles in verbal, physical and relational bullying in preschool children. A possible explanation for this might rely on the fact that the development of theory of mind skills depends on maturation processes such as the development of pre-frontal lobe (Sabbagh et al., 2009). It seems therefore that theory of mind skills may play a role in victimization processes for older children when they acquire second order skills such as interpretative theory of mind (Chandler & Lalone, 1996). In relation to the cognitive aspects of empathy, our results showed that this may be an important factor for children not assuming any central role in verbal bullying episodes only. In line with our findings, Endreson and Olweus (2001) and Espelage, Mebane and Swearer (2004) showed that middle school children who scored high on empathy tended to avoid engagement in bullying episodes. However, there was no main effect of empathy scores for both physical and relational bullying. As far as hostile bias are concerned, our data revealed that children not assuming any central role are better, rather than the victims, at attributing hostile intent to actions relevant to relational bullying, and therefore be able to recognize and avoid engagement. According to our findings, perpetrators of physical and relational bullying tended to report more hostile strategies than victims or children not assuming any central role.

As far as the social context is concerned, bullying episodes were more frequent when children were involved in joint compared to group or solitary play activities. It seems that in the preschool victimization interactions manifests primarily during dyadic activities where it would be easier for the perpetrator to manipulate a target. According to our results, preschool children were capable of organizing group bullying acts. Almost one out of three of the episodes recorded were attacks directed to a victim by a whole group of peers. Our results imply that bullying might be a social phenomenon even in the early years. This is extremely important since research data investigating the occurrence of group bullying in this young age group is extremely scarce. Past studies based on peer nominations or teacher reports implied that peripheral roles in preschool children might not be as salient (Monks et al., 2003, 2005). The results of our observational data show that children undertake peripheral roles. According to our observations, preschool peers were present in almost eight out of ten bullying episodes. Of those children present, the majority watched passively the event, a considerable percentage supported the bully and a small percentage defended the victim. A possible explanation for this comes from our finding that the perpetrators' behavior tended to be influenced by the reactions of children standing by. When observers or assistants were present during the episode this seemed to work as reinforcement for the aggressive reactions of the bully. According to Twemlow, Fonagy and Sacco (2010), the role of the observer entails active involvement and for this reason it should not be considered as neutral. Children who simply watch bullying will often contend that they "aren't doing anything". In their observations, O'Connell, Pepler and

Craig (1999) found that peers reinforced bullying 54% of the time by passively attending to the episode and not helping the victim. Besides, and according to our results, preschool victims reacted mainly in a passive and submissive way. This is in line with previous research which found that submissiveness is the hallmark of victimization (Perren and Alsaker, 2006). Also, in our study, when preschool teachers were physically present they intervened to help the victim at a higher rate compared to prior research data conducted with school teachers (Craig and Pepler, 1995, 1997; Salmivalli and Voeten, 2004). A possible explanation for this finding is that preschool children are more dependent and rely more often on adult attendance than school children. Therefore, teachers working with young populations tend to be more considerate and observant than school teachers. In relation to this, Jimerson, Swearer and Espelage (2010) argue that the social context in the school constitutes a substantial factor when examining bullying behavior. Teachers' attitudes and interventions could contribute significantly to the decrease of victimization prevalence (Biggs, Vernberg, Twemlow, Fonagy, and Dill, 2008; Jimerson et al., 2010). In line with previous research (Craig and Pepler, 1995, 1997; Salmivalli and Voeten, 2004), we found that bullying episodes occurred more frequently when adult supervision is not active. Furthermore, our results showed that when bullying episodes occurred into the classroom supervision was more frequently active compared to supervision on the playground. Support for the above finding comes from prior data where most children, knowing that aggression is prohibited, restrict their aggression toward peers to the less supervised locations of the playground, or out of the sight of adult supervisors (Pellegrini, 1990). Nevertheless, preschool children were observed to demonstrate bullying behaviour at a relatively high percentage even when supervision was active. This may imply that preschool perpetrators act in a more impulsive and less prohibited way than their school-age counterparts.

In our study, teachers tended to act passively when victimization processes occurred in the non-specified locations of the playground. A possible explanation is that teachers, in this specific location, might have mistaken bullying episodes for rough-and tumble play. Support for this comes from a study of Blatchford (1996) where a high percentage of school personnel continued to view recess as a carefree and positive play period for children. It is thus important to include teacher sensitization and training when designing effective prevention programs (Hazler, Miller, Carney, and Green, 2001). As far as the physical environment is concerned the findings from the present study indicate that bullying episodes occurred into the specified locations of the preschool class more frequently than on the playground both in the non specified areas and the specified ones. Contrary to the formal school settings, the structure of the preschool class might incite children to engage into victimization processes. More specifically, the preschool space is particular in that it is separated into learning areas where children interact and move with greater freedom whereas a typical school class is organised and arranged in a way that pupils' interactions and mobility are restrained. For this reason, school-age children may find it easier to organise bullying attacks during recess on the playground rather than into the classroom.

Another interesting finding is that group bullying is independent of bully's gender. Given that boys prefer to play in large and open play groups whereas girls' playgroups are usually in dyads (Bugental, 2000), one would expect boys to carry out more frequently group attacks. Rather, our findings highlight that girls organise group attacks as frequently as boys. Moreover, neither cognitive empathy, nor theory of mind and hostile bias and strategies influence group bullying. This means that those psychological correlates do not play an important role when group bullying behaviour is displayed. Finally, ring-leader bullies organising group attacks are

popular amongst their peers whereas perpetrators organising sole attacks tend to be rejected by their peers. Support for this finding come from outcomes of a recent study examining the resource control theory in preschoolers' behaviour (Roseth, Pellegrini, Dupuis, Bohn, Hickey, Hilke, Peshkam, 2011). It was shown that coercive resource control was used most frequently at the start of the school year, presumably to access resources and establish social dominance. Rates of prosocial resource control increased over the school year, and socially dominant preschoolers showed higher rates compared with peers, presumably to maintain resource control while keeping peers as allies. Socially dominant preschoolers also used reconciliation more often than peers, resulting in higher rates of affiliation between former competitors and more positive peer regard from fall to spring. Therefore, ring-leader bullies tend to be more popular probably due to their ability to interchange between coercive and prosocial strategies whereas single bullies tend to use coercive strategies and hence experience peer rejection. In line with this, an investigation carried out in elementary school children highlighted the importance of distinguishing between (1) strategic social-cognitive and moral competencies and (2) different subgroups of bullies (Gasser & Keller, 2009).

EDUCATIONAL IMPLICATIONS

The implementation of effective prevention programs, as early as in the preschool, is critical. The fact that preschool bullies demonstrate aggressive behaviour even when supervision is active may help teachers to intervene actively and prevent victimization processes from escalating. Also, preschool teachers should be particularly attentive in the non-specified interior places, i.e., corridors, toilets, where perpetrators are capable to isolate their victims. According to our findings, the role of the observer during victimization interactions in the preschool is active and critical; it can be either favourable or detrimental. Therefore, primary prevention programs should include developmentally appropriate activities informing preschool children about the process of victimization and should focus on training them to implement strategies to defend victims. Finally, the results of the present study have shown that bullying is a social phenomenon and involves a whole group of persons even in the preschool. One out of three attacks were organised by a whole group of peers. The fact that the majority of episodes occurred during social play activities means that anti-bullying prevention programs should take the development of social play processes into account. As far as the physical environment is concerned, our results show that bullying episodes occur into the specified locations of the preschool class. Space arrangement and classroom general layout play an important role in the occurrence of bullying episodes. Particularly important is the consideration of the overall classroom arrangement, especially in spaces that remain unspecified in children's use; for instance, teacher areas, large open spaces, and walk through pathways leading to other classrooms. Planning of every space is essential in ensuring positive social interactions among children (Harms et al., 1998; Peisner-Feinberg, Burchinal, Clifford, Culkin, Howes, Kagan, et al., 2000). Therefore, certain arrangements should be made into the classroom in order to ensure positive peer interactions, i.e., environment quality, abundance of materials, arrangement of learning corners, setting rules etc.

LIMITATIONS - FUTURE RESEARCH

It is a fact that during our naturalistic observations, the presence of observers, although unobtrusive, might have altered children's behaviour. It might be difficult to observe and evaluate children's playground aggression because adults may not always be aware of the aggressive incidents that occur privately between peers (Cairns and Cairns, 2000; Pellegrini, 1995). Therefore, future research should seek to triangulate data collected through observations. Also, given the distance and noise present on the playground, observers might have been unaware of verbal or relational playground aggression that has occurred. Future research should seek to examine in depth those parameters of the preschool context, both into the classroom and on the playground, that influence bullying behaviour. For example, it could be interesting to compare space arrangement and layout from different preschools and find out the degree to which those parameters correlate to each other. Bullying behaviour is largely influenced by the social environment of the school. It would be interesting to examine which personality traits influence the attitude and behaviour of children present (observers, assistants, reinforcers, defenders). Qualitative data are also needed in relation to group bullying, its occurrence and underlying aetiological factors. Cross-sectional or longitudinal studies comparing peripheral roles and group bullying between preschool and school-age children are needed in order to design effective prevention programs. Finally, future research should examine prevention programs that include developmentally appropriate activities in relation to social play in preschool children.

In relation to the role of empathy, a recent study, using teacher reports, showed a robust negative relationship of both affective and cognitive empathy with hostile roles and with outsider role, contrary to a positive correlation of only affective empathy with prosocial roles. No relationships emerged between empathy measures and victim role (Belacchi & Farina, 2012). In our study, only cognitive empathy was measured using observational data in relation to central participant roles. Future research would seek to examine the mediating role of both affective and cognitive empathy in relation to central and peripheral roles using observational data in preschool children. Recently, it was revealed that only bully-victims, but not bullies, were characterized by a deficit in perspective taking, while both aggressive groups showed a deficit in moral motivation (Gasser & Keller, 2009). Future research in pre-school populations should seek to understand the implication of perspective taking and moral competencies (moral knowledge and moral motivation) in victimization processes among preschoolers.

CONCLUSION

Bullying is a social phenomenon even in the preschool. Both the physical and social features of the school environment affect the occurrence of victimization. The results of the present research showed that, apart from central peripheral roles, active supervision, teacher sensitization, bystander's role, group bullying and space arrangement for social interactions should be thoroughly examined when studying the emergence of bullying behaviour. All in all, we would argue that mediating factors influencing victimization processes should be investigated in preschool contextual factors such as socialization processes rather than in intra-personal factors such as socio-cognitive skills. Pro-bullying behaviour, in preschool children,

may generate when children enter preschool contexts, develop through peer interactions and establish during socialization processes, i.e., friendship liaisons.

APPENDIX

Scoring/Coding

- 1) For central participant roles, children were scored as perpetrators if they initiated an unprovoked aggressive act towards their peers. The bully was clearly the leader in the episode. The victim was the recipient of the act by a more dominant individual. Also, children were scored as bully-victims when they were observed to display dual role behaviours.
- 2) The forms of bullying recorded were: *physical bullying* (i.e., hitting, pushing, pulling, punching, or forcibly taking objects), *verbal bullying* (i.e., antagonistic teasing, mean names, verbal threats of harm, or insult not expressed at friendship status; i.e., 'Shut up!', 'Chicken!' etc), and *relational bullying* (excluding from playgroup, withdrawing friendship, maliciously telling lies, ignoring a peer; e.g., 'You can't play with us but she can,' 'You can't come to my party,' or deliberately turning away and ignoring a peer's request to join in play). Social exclusion involved the rejection of an individual from a group. It was only considered to be bullying when the exclusion was related to the child, not the nature of the activity from which they were excluded. If, during an episode, a focus child was observed to demonstrate or receive more than one form of bullying behaviour then the roles corresponding to those forms of bullying were checked i.e., a focus child demonstrated social exclusion and physical bullying during the same episode then the role of perpetrator was checked for both forms of behaviour for the same child.
- 3) Playful activities were scored according to the following categories: 1. Solitary play: refers to children who play all alone, 2. Joint play: refers to a pair of children playing together, and 3. Group play: refers to groups of three or more children who are actively playing together.
- 4) It was also noted whether the episode took the form of group bullying. Scores for this variable were dichotomous (yes/no). Group bullying was scored anytime an aggressive act of two or more children was directed towards a sole child.
- 5) For the peripheral roles, children were scored as observers, assistants, reinforcers and defenders. More specifically, observers were children who were in close proximity and merely watching the bullying episode. An assistant was a child who co-operated with the bully but did not initiate the act. The reinforcer referred to the child who joined in the episode but did not initiate the attack nor shared major responsibility, i.e., laugh while a victim is humiliated. Defenders were children who took the victim's side, supported or consoled the victim, and/or intervened in bullying on behalf of the victim.
- 6) A brief description of the reactions of the victim, the bully and the supervisor (if present) were recorded. Based on our field notes, codes for the reactions of the bully and the victim were selected and classified in the following categories as: 1. aggressive, i.e., beatings, kicks etc, 2. prosocial, i.e., shows social behaviour, 3.

passive, i.e., does nothing, and 4. speaks to the teacher. The reactions of the teachers were recorded as: 1. passive, i.e., does not react, watches inactively, 2. speaks to the child, i.e., tells children to stop it, to play carefully, 3. resolves immediately the conflict, i.e., separates the bully (ies) from the victim(s), sanctions the bully, tries to integrate a socially excluded victim.

- 7) The presence of active adult supervisor was also noted down. Active supervision was defined as either the physical presence of the teacher maintaining direct visual contact or as being attentive to children's interactions i.e., talking to the group of children, maintaining unobstructed supervision (hindrance from furniture), standing at a close distance from children during outdoor activities.
- 8) For all episodes, the location of the event was recorded. More specifically, we noted whether the event occurred into the classroom (or the locations close to the classroom) or on the playground. For each location it was, also, noted whether the location was specified or non-specified. Specified places refer to all organised areas equipped with educational materials/structures i.e., into the classroom the learning areas e.g., reading area, arts etc, and on the playground the areas for psycho-motor play, i.e., sliding frames, bowling etc. Non-specified places are those "open" spaces offering no organisation at all i.e., free open play spaces, the open space surrounding the "circle". Also, we recorded bullying episodes that took place in the areas adjacent to classroom such as the corridors, toilets, storage sheds. Those areas were considered as open "classroom" spaces, since in the preschool context children are free to move or interact into those places during free play activities.

Criteria for Identifying Bullying Episodes

Bullying is defined as an intended and unprovoked aggressive act which is carried out repeatedly and is characterized by an imbalance of power. During observations and in order to distinguish aggressive from bullying acts we followed the above criteria.

Negative intent is difficult to quantify because we cannot see what one is thinking. However, negative intent may be exhibited through facial expressions or verbalisations of intent. Therefore, in the present study participant roles were attributed when negative, unprovoked acts (the perpetrator displayed proactive aggression) were directed towards a weaker peer. For our data analyses, only those participants who were observed to act more than once as either perpetrator and/or victim for the same form of bullying were assigned the corresponding role. Roles were attributed independently from the interaction between two children. For example, the role of perpetrator for physical bullying was attributed to child A if it kicks child B and next child C, and/or kicks child B into the classroom and child C on the playground. Therefore, the criterion of repetition "more than once a week" was fulfilled. Also, we have selected only those negative interactions where an imbalance of social power or physical strength was observed among participants. Counts were made each time a behavior occurred, i.e., one insult added one episode, two insults added two episodes and so on. One episode was marked even when the behaviors were part of the same encounter. If a child maintained a continuous aggressive act i.e., a pinch for an extended period of time, only one episode of physical bullying was made. Similarly, the continuous statement, 'We don't like you, so you can't play with us' would be coded as one act of relational bullying rather than two,

given the immediate temporal association and interdependency between the two phrases. Two episodes were counted if the victimization acts were observed in different contexts and therefore were distinct. When an act was not intended i.e., a ball that sailed out of control and hit another child, it was not an event that scored as an aggressive act.

Chapter 95

DISCORDANCES IN ADOLESCENTS' ADOPTION OF PERSPECTIVES ON BULLYING, AND THEIR IMPORTANCE FOR DEALING WITH THE PROBLEM

Isabel Cuadrado-Gordillo and Inmaculada Fernández-Antelo
University of Extremadura, Spain

ABSTRACT

In recent decades, the phenomenon of school violence has been the subject of numerous studies. These have elucidated the dynamics of the bullying and victimization that occurs in schools, and explain in part some of the imbalances and conflicts detected in pupils' relationships with each other. Current interest is focused on studying the adolescents' own perceptions of bullying. Finding answers to such questions as what they understand by bullying, whether there are differences in their conceptions and if so what causes these variations, what types of behaviour they consider to be bullying or which criteria they use to sometimes classify a form of behaviour as bullying and sometimes as aggression or a reprimand, will allow the phenomenon to be better understood and delineated.

The aim of the present work was to contribute to a better understanding of the potential risk factors and predictors of school bullying. It analyses the perceptions that 2295 Spanish secondary school pupils (aged from 12 to 16 years) have of bullying, and the different forms in which it occurs (physical, verbal, social, sexual, etc.). The most relevant contributions of the work reside neither solely nor primarily in the description of how the pupils may conceptualize bullying, but in analysing the principal variables affecting their perceptions – the role they themselves play in these situations (aggressor, victim, or witness), gender, intensity of the aggression/victimization, and age or educational level.

The results showed that a pupil's perception of bullying and its different modalities depends on the role he or she plays in situations of school violence. Aggressors emphasize the criterion of "power imbalance", and often justify many of the situations usually described as bullying as really being just another form of adolescents' social interaction. Victims are less likely to use this type of justification, but instead emphasize as the main defining criterion of bullying the "intent to hurt". Witnesses see both of these conditions as being necessary to classify aggression as bullying – that the aggressor has a clear intention

to hurt the victim, and that there is a power imbalance between victim and aggressor in favour of the latter.

With respect to gender, there were significant differences between boys' and girls' perceptions of the different modes of bullying and the type of behaviour that it involves. Similarly, the results for the variable intensity of aggression/victimization indicated that as the intensity increased, there was a corresponding decrease in the pupils' identification of aggressive behaviour with mechanisms of social interaction. With respect to age, the older pupils presented the fullest and most detailed perceptions of the phenomenon of bullying, but they also were more likely to downplay certain aggressive manifestations, considering them to be typical forms of interaction among adolescents.

INTRODUCTION

The dynamics of the bullying and victimization among peers that take place in school has been extensively studied over the last more than thirty years. During this period many varied programs of prevention and intervention have been implemented, but still the problem persists. In all schools there are still bullies who abuse their peers, and victims who suffer the aggressions of maybe just one student, or a group of students, or classmates hiding behind the anonymity of the Internet. And surrounding the bullies and the victims is a great mass of witnesses who pull a veil of silence down to cover these episodes of violence, and thus themselves contribute to the persistence of the aggression.

This lack of effectiveness in solving the problem may in large part be due to the difficulty in clearly defining and delimiting the bullying phenomenon.

The World Health Organization (2002) identifies bullying as a deliberate use of force or power, physical or psychological, as a threat or an actual event, which occurs against oneself, another person, or against a group or community with intent to cause injury, death, psychological harm, or deprivation. However, this definition takes on different nuances, even significant variations, for the different research contexts in which this phenomenon and its manifestations are studied. Espelage & Swearer (2003) note also that the concept of bullying not only varies with from researcher to researcher, but also with the country in which it is studied. Smorti, Menesini & Smith (2003) show that there are significant differences in the concept of bullying between Japan, Italy, Spain, England, and Portugal. Their results indicate that the linguistic richness of each language interferes sometimes in the translation of the term bullying, since there may exist different expressions and terminologies that approximate the meaning given to it in English. This terminological variability can bring about confusion and a lack of precision, with aggressive forms of behaviour being labeled as bullying when they are not.

But beyond language difficulties, what is detected is a lack of consensus in establishing objective criteria and quantifiable measures to catalogue violent behaviour as bullying. One of the most accepted and widespread conceptions is that bullying is any behaviour used repetitively by a person who has more physical, social, or psychological power than his or her victim and is committed with intent to cause harm, either physical or psychological. From this definition, three basic criteria can be drawn that facilitate its identification – the repetition of violent behaviour, the imbalance of power between aggressor and victim, and the intention to hurt.

Regarding the 'repetition' criterion, Dam Olweus, one of the researchers who has most studied bullying in schools, indicates that in some circumstances a one-time attack can be considered bullying behaviour (Olweus, 1993). The problem generated by this affirmation is that it has not yet been determined what those circumstances would be. Similarly, other researchers also suggest that a single occurrence of aggressive behaviour can be labeled as bullying if it causes negative effects on the victim that last over a prolonged time period (Arora, 1996; Randall, 1996, Guerin & Hennessy, 2002), but neither here is it clearly laid out how long that period would have to be.

The discrepancies also extend to the 'power imbalance' criterion. Tatum (1997) states that the superiority of the aggressor over the victim does not have to be real – it is sufficient that the victim perceives it as such. In either case, the behaviour leads to the victim feeling helpless and unable to cope with the situation because he or she believes that their abuser can repeat it even more viciously as having greater physical, psychological, or social strength. This leads us to consider that the perception of the asymmetry of power often lies in the physical or social image of both the aggressor and the victim.

In the case of the perception of physical power imbalance, the aggressor is associated with someone more corpulent, muscular, and bigger than the victim, whose body image is weak and fragile. However, for adolescents it is the social asymmetry and fear of exclusion from the peer group that is becoming more important. In this case, the image of the aggressor does not always coincide with that of the most popular person, which makes it difficult to identify the signs or characteristics that identify the possible existence (real or imagined) of power imbalance. It is even more difficult to discover the criteria the victims use to perceive asymmetry of emotional or psychological power. As suggested by Dooley, Pyzalski & Cross (2009), it is becoming steadily more complex to capture the repetitive nature and the power imbalances to which the current definitions of bullying refer.

Finally, the 'intention to hurt' criterion also raises some questions among researchers that hinder the identification of episodes of bullying and therefore of practical intervention. Tatum (1997) rejects the existence of an actual intent to hurt the victim by the aggressor, and explains that behaviour may be classified as bullying if it caused any harm to another person, regardless of the intent with which this behaviour had been carried out. Thus, it may be that someone feels harassed and injured without their alleged aggressor knowing or having had any intention of assaulting them, but instead with the act having been accidental. It is enough that the victim perceived, wrongly or not, that someone else had an intention of hurting them for that conduct to be labeled as bullying. However, a majority of researchers still state that the aggressor must intend to cause harm for violent behaviour to be classified as bullying.

These discrepancies between researchers in the conceptualization of this phenomenon may have a significant influence on the results of epidemiological studies aimed at detecting the numbers of aggressors and victims, as it may be that some researchers consider some individuals as bullies that other researchers do not categorize as such. Furthermore, if there is no unanimous agreement that allows the identification of those involved in bullying situations and of the roles they play, then the results of comparative studies between countries, communities, or even schools should be taken with some caution.

The difficulties that researchers have in defining and identifying bullying situations are significantly multiplied when it is adolescents who have to do the defining and identifying. In recent years we have conducted extensive research focused on the study of the perceptions of adolescents regarding bullying and its manifestations in the school context. The ultimate goal

is to design more effective prevention and intervention programs. If researchers use different criteria to those used by students to classify violent behaviour as bullying then they will be describing different realities, and the success of any such programs will consequently be severely threatened.

HOW ADOLESCENTS DEFINE SCHOOL BULLYING

One of the basic premises defended by most of the researchers who analyse the bullying phenomenon is the coexistence of three identification criteria: repeated aggressive behaviour, supremacy of power on the part of the aggressor, and a manifest intention to cause harm to the person against whom the aggression is directed. However, studies conducted in many countries conclude that very few adolescents employ these three criteria together to identify signs of bullying. This means that many young people label as bullying isolated assaults that probably involved no intention to cause harm, or types of behaviour that may not be violent but are nonetheless hurtful to certain people, or abuse that is repeated continuously but does not really have a victim, etc. But the opposite may also occur. We find adolescents who do not consider as bullying a repeatedly produced aggression with a clear intent to harm a person who is at a lower status than their attacker.

The analysis of the different criteria used by young people to identify bullying situations will allow a closer understanding of their perceptions and a better match of the measures aimed at improving school life to the realities of that context.

The most controversial of the criteria in the definition of bullying is that of repetition of the abuse. Indeed, there are still numerous ongoing debates about the frequency and extension over time of aggressive behaviour. For some researchers this criterion is met when the abuse has been committed several times in recent months, but others consider that the repetition rate has to be weekly. These difficulties in the operational definition of the frequency variable is not shared by the adolescents who, for the most part, do not refer to this criterion in their concept of bullying. The studies of Madsen (1996) in the United Kingdom indicate that 97% of the secondary school students participating in the research did not believe that the repetition of aggressive behaviour should be a condition determining the classification of the behaviour as bullying. In 2006, in the same country, Naylor and co-workers confirmed the lack of importance that students of 11 to 14 years old attributed to the repetition criterion, finding that 91% of the 1820 adolescents surveyed did not use it in their definitions of bullying.

In other countries the figures are similar. In Canada, Vaillancourt and co-workers (2008) found that 94% of a sample of 1767 students did not mention repeated abuse in any of their definitions of bullying or in their identification of its manifestations. In Ireland, the percentage drops to 72.3% (Guerin & Hennessy, 2002) and in Sweden to 70% (Frisén, Holmqvist & Oscarsson, 2008). Other studies do not provide exact percentages but indicate that students rarely refer to the repetition criterion to define bullying, e.g., Cheng, Chen, Ho & Cheng (2011) in a study conducted in Taiwan with 967 secondary school students. The research conducted in Spain by Cuadrado (2011) with 2295 adolescents also shows that for adolescents the repetition of the abuse is not a criterion for identifying or defining bullying. In the United States, Land (2003), on a sample of 147 students from 14 to 18 years, states that less than half of those adolescents considered the repetition as a requirement for the classification of aggressive

behaviour as episodes of bullying. In sum, all these studies note that for many young people a single occurrence of violent behaviour that causes harm to another person may be perceived as a manifestation of bullying.

A second identification criterion that achieves greater consensus among researchers is the 'intention to hurt another person'. However, a major fraction of adolescents believe that bullying is any behaviour that causes physical, psychological, or social harm to another person, even if there was no intention to do so. In this sense, Everett & Price (1995) found that only 17% of the 726 adolescents surveyed perceived in the aggressor an intent to harm. This percentage decreased significantly in other studies addressing the perceptions that secondary school students have of bullying. Guerin & Hennessy (2002) report 13%, while Madsen (1996) only 5%, Naylor et al. (2006) 3.9%, and Vaillancourt et al. (2008) 1.7%. However, the use of different data collection instruments and the variability in the size and composition of the sample may in part explain such mixed results. Hunter, Boyle & Warden (2007), in a study of 1429 Scottish pupils of 8-13 years old, concluded that for these young people the attribution of the aggressor's intention of doing harm is a very difficult aspect to detect and measure, with the consequence that sometimes this criterion appears very pronounced in the definitions given for bullying, and sometimes it is absent. Some researchers, such as Cheng et al. (2011), reflect a different situation, indicating that the majority of adolescents believe that the intent to cause harm should be the central support of the definition of bullying. What is more complex to determine is whether that intention is real or the result of a subjective perception on the part of the victim. Indeed, Cuadrado (2012) warns that this variability in the responses of adolescents is even greater if one considers the role each participant plays in the bullying situations that occur in their school – in particular that the perception of intentionality is much commoner in the victims than in the aggressors.

Finally, regarding the criterion 'imbalance of power', the results of research addressing this issue have also been very different, leading to new questions concerning the causes of this variability, especially the influence of cultural identity. Thus, while Frisé et al. (2008) find that 19% of adolescents conceive the imbalance of power between aggressor and victim as a condition to define an episode of aggression as bullying, for Naylor et al. (2006) the proportion rises to 40%.

Differences in Adolescents' Perceptions of the Manifestations of Bullying

The difficulties adolescents have in conceptualizing the term bullying increase when it comes to determining its possible manifestations in school. Their doubts are generally focused on the more indirect or less obvious forms of behaviour. In this regard, Boulton, Trueman & Flemington (2002) note that the behaviours that students most often classified as episodes of bullying are those in the form of direct physical aggression. In this case, these authors indicate that 82.9% of adolescents consider fighting and jostling as possible manifestations of bullying. At the opposite extreme is behaviour related to isolation and social exclusion, which are mentioned by only 20.6% of the students. Between the two extremes are threats that are included among the forms of bullying by 72.7%, direct verbal aggression and more specifically the allocation of offensive nicknames by 65.9%, indirect physical abuse (such as taking personal property away so as to annoy, or ridiculing the victim before their peers) by 59.4%, and indirect verbal aggression (such as spreading false stories and rumours) by 54.1%.

These percentages differ from those found in other studies such as those of Menesini, Fonzi & Smith (2002), Guerin & Hennessy (2002), Naylor et al. (2006), Friséen et al. (2008), and Vaillancourt et al. (2008), although they all agree in pointing out that the modalities of bullying that teenagers identify most easily are those of direct verbal and physical abuse, while those they find most complex involve social isolation. In this regard, the studies by Menesini et al. (2002) indicate that the proportion of students who refer to physical abuse such as hitting, kicking or punching reaches 97%, and references to verbal attacks are made by 90.5%. These figures drop in the work of Naylor et al. (2006), where 65% of adolescents see physical abuse as potential signs of bullying, and 60% also include direct verbal insults or offensive nicknames. The percentage of students who see behaviour oriented towards provoking social exclusion as possible episodes of bullying is also low, being just 5%, while the proportion reported in the study of Guerin & Hennessy (2002) is 13%.

The student's Gender as an Explicative Factor of the Variability in the Perception of Bullying

The differences found in the concept of bullying taking the gender of the students into account refer to the relative emphasis that boys and girls give the various criteria used to discriminate a bullying situation from other violent acts. The works of Naylor et al. (2006) and Friséen et al. (2008) suggest that boys refer more often than girls to the criterion of 'imbalance of power'. However, no significant differences were recorded in the criteria of 'repetition' of aggressive behaviour or of the 'intent to cause harm'.

In relation to the variability in the consideration of the possible manifestations of bullying, Crick, Casas & Ku (1999) indicate that previous experiences of aggression or victimization that the young people have had to a great extent conditioned whether they included the corresponding modality in their conception of the phenomenon. If this premise is true, one should be able to anticipate which manifestations of bullying would most often be mentioned by the girls and which by the boys. We know that the majority of studies examining the incidence and types of bullying have concluded that girls are more likely to commit and suffer verbal aggression and behaviour that leads to social exclusion, while boys usually resort to direct physical abuse.

The above predictions are confirmed in the research of Smith et al. (2002), Naylor et al. (2006), Friséen et al. (2008), and Vaillancourt et al. (2008) who find that, relative to the boys' perceptions, in the girls' it is usual to find a greater proportion of references to forms of bullying which include relational types of aggression, such as social exclusion or spreading false rumours. They also find that the verbal abuse modality of bullying also tends to be more frequent in the girls' descriptions.

How the Student's Age Influences Their Perception of Bullying

Changes in the conceptualization of bullying attributed to the age variable refer firstly to the development of cognitive abilities. Comparing children of 7-9 years with adolescents, one will quickly observe that the formers' interpretations focus more on the results of the actions than on the intent with which they are committed. However, with increasing age, attention is

not directed solely to the results but takes other dimensions and more complex categorizations into account, facilitating a more detailed and complete understanding and explanation.

Secondly, differences in perceptions of bullying may also be motivated by previous experiences of victimization or aggression. The likelihood of having committed, experienced, or observed a greater number and diversity of bullying episodes is substantially greater in an older child (Monks, Smith & Swettenham, 2005).

HOW THE ADOLESCENT'S ROLE IN BULLYING SITUATIONS AFFECTS THEIR PERSPECTIVES ON THE PHENOMENON: AN EMPIRICAL STUDY

The experiences, direct or indirect, of bullying situations exert an influence on the perception that adolescents have of this phenomenon and its possible manifestations in the school (Astor, Benbenishty, Vinokur & Zeira, 2006). Young people who have studied in schools where peer aggression occurs frequently tend to have a more complete and consistent definition of bullying than those who have not been exposed to this type of situation, or only very occasionally. However, the authors of that study do not specify what influence those experience actually has, or if there are differences as a function of the intensity or the type of those experiences, or of the student's role in the situation (aggressor, victim, or witness).

In the present work, we try to answer these questions by presenting the results of research carried out in Extremadura (Spain), involving 2295 adolescents (54.3% male and 45.7% female, $SD = 0.4$) with ages between 12 and 16 years ($M = 13.8$, $SD = 1.4$). The instrument used for data collection was a questionnaire designed and validated for this study. The questionnaire was designed first to identify students who are aggressors, victims, and witnesses of school bullying situations, and the frequency with which they commit, suffer, or observe such situations. In this latter case, the scale used consisted of four values: Never, Sometimes, Often, and Always.

Second, the study shows which are the criteria adolescents use to identify an episode of bullying and differentiate it from other acts of violence. And third, it allows one to determine whether or not those criteria are the same for the various modalities of bullying. In these latter two cases, the response scale consisted of five values: Strongly Agree (1), Agree (2), Neither Agree Nor Disagree (3), Somewhat Agree (4), and Disagree (5).

From the data collected with the questionnaire, it was necessary to make an initial factor analysis to reduce the number of variables to consider, reflecting the main factors explaining the variability, with the relative importance of each and the relationships between them. Further exploratory factor analyses allowed us to know whether the criteria resulting from the above analysis are applied equally by aggressors, victims, and witnesses, and whether there is any variation depending on the intensity of the abuse committed, experienced or observed. Finally, to detect and evaluate possible gender differences, we made a contingency analysis assuming a confidence level of 95% ($\alpha = .05$) and a sample error estimated at around 2.1%.

Delineating the Criteria Identifying Bullying

The approach to the perceptions that adolescents have of this phenomenon requires knowledge of both the factors or criteria that shape their definitions of this concept and of what they think are the possible behaviours in which bullying may be manifest in their school context. For adolescents, the definition of this construct may be complex. However, the detailed description of its application was expected to be simpler for them, and would thus facilitate our acquisition of a more global and comprehensive vision of the bases of their perceptions of bullying.

The diversity of the responses required the application of a first exploratory factor analysis to group the responses depending on their interrelationships, and thus delimit more generic criteria. The resulting KMO index of .82 and a significance level in the Bartlett sphericity test of .001, provided the sufficient guarantee of reliability of the results.

The principal component analysis showed that, although in principle up to 7 factors were detected as present in the concept students have of bullying, only 3 explain the variability of the responses and provide a closer approximation to the general perception that more than 83% of the participants has (Table 1).

The resulting factors were the following:

Factor 1. A form of social interaction. This factor encompasses bullying situations that the teenagers interpreted as a form of amusement and peer relationships. It explained 48.68% of the variance (Table 1), and had a moderate internal reliability ($\alpha = .61$) and a mean factor loading of .54.

Factor 2. Intent to hurt. This factor includes the responses in which the teens considered the intent to cause physical, social, or psychological harm in others as a necessary condition for aggression to be classified as bullying. It explained 22.56% of the variance (Table 1), and had an internal reliability of $\alpha = .69$ and a mean factor loading of .52.

Factor 3. Power imbalance. This factor includes behaviours that the teenagers classified as bullying and in which they perceive the aggressor to have some superiority over the victim. It explained 12.6% of the variance (Table 1), and had a high internal reliability ($\alpha = .85$) and a mean factor loading of .77.

Table 1. Total Variance Explained by the Components

Component	Initial eigenvalues			Sum of the squared saturations of the extraction		
	Total	% of variance	Accumulated %	Total	% of variance	Accumulated %
1	5.93	48.68	48.68	5.93	48.68	48.68
2	2.75	22.56	71.23	2.75	22.56	71.23
3	1.53	12.6	83.83	1.53	12.6	83.83
4	0.91	7.47	91.3			
5	0.74	6.11	97.41			
6	0.22	1.77	99.19			
7	0.1	0.82	100			

Extraction method: principal component analysis.

The comparison between the criteria assumed by researchers and those adopted by students indicates that they both agree that there must be an asymmetry of power between victim and aggressor, and that the aggressor's intention to hurt should be perceived. But the 'repetition of aggressive behaviour' is hardly represented at all in the students' descriptions and definitions, and represents neither a basic nor an identifying criterion.

Table 2. Rotated component matrix

	Components		
	1	2	3
Definition of bullying		.761	.503
Social isolation	.619	.393	
Not letting the other participate in class	.573		
Insults	.372	.442	
Spreading false rumours	.623		
Nicknames	.864		
Negative criticisms	.361	.427	
Ridiculing others		.614

Direct physical aggression			.917
Intimidation			.815
Forcing others to do things against their will			.836

Extraction method: principal component analysis.

Rotation method: Varimax.

The rotation converged in 4 iterations.

The results reveal the presence of a factor explaining 48.68% of the students' responses that referred directly to their perception of certain types of behaviour labeled as manifestations of bullying. This is the perception of certain types of behaviour as mediating elements that facilitate and promote peer relationships.

However, the results presented in Table 2 show that the presence of these three factors undergoes major changes depending on the mode of abuse being considered. Also, there are differences when comparing the concept of bullying as a global phenomenon with its manifestations in the school context alone (Table 2).

Regarding the definition of bullying, the adolescents refer to the criteria of intentionality and power asymmetry, with the former predominating. When asked about the different manifestations of bullying listed in Table 2, none of them consider these two criteria (intentionality and power asymmetry) simultaneously, and they consider 8 of the 12 types of behaviour described as 'forms of social interaction'. Some of these reach important factor weights, in particular the forms of social exclusion, verbal abuse, and indirect physical abuse. However, some of these types of behaviour also recorded significant scores on the criterion 'intentionality'. It remains to determine whether this seemingly contradictory duality of scores is motivated by their experiences or by the contextualization they make of the scenes described. The detailed analysis to be presented below of the perceptions in terms of the role played may shed more light on this issue.

Also, the results in Table 2 show that there is a broad consensus among adolescents that the fundamental criterion for classifying as bullying some direct physical aggression, or the different types of threats, is the imbalance of power between the aggressor and victim. This explains the high factor scores in these cases (.917, .815, and .836).

Gender Differences in the Perception of Bullying

The gender differences detected in the perception that adolescents have of bullying refer to the emphasis each gender gives to the identifying criteria (Table 3). The girls' scores were higher on both 'power imbalance' and on 'intent to harm' ($p < .01$).

Regarding the differences found in the perception of the different types of bullying, boys attributed more than the girls the 'intent to harm' to behaviours that lead to exclusion from peer groups and social isolation ($p < .01$). But at the same time, the boys more frequently tended to explain the manifestation of this type of behaviour as a mechanism facilitating interaction between peers, permanence in the group, and the respect of peers ($p < .01$).

Verbal insults are perceived by both boys (52.7%) and girls (56.5%) as forms of aggressive behaviour intended to ridicule others in front of peers and to cause them suffering. However, 29.8% of boys and 48.1% of girls do not consider such insults as a form of bullying, but as a teenage vocabulary that allows them to relate to each other ($p < .01$).

Another form of conduct included in the modality of verbal aggression is 'spreading false rumours'. The results show that most students perceive this behaviour as a common consequence of the relations established between peers, and that it is more frequent in girls than in boys ($p < .05$).

Table 3. Gender differences in the perception of bullying (%)

	Components					
	Power imbalance		Intent to hurt		A form of social interaction	
	Men	Women	Men	Women	Men	Women
Forms of bullying						
Definition of bullying	26.8	32.7**	53.5	59.7**	1.7	1.3
Social isolation	11.7	9.5	38.7	30.6**	63.5	44.0**
Not letting the other participate in class	8.2	9.1	21.4	22.3	59.9	55.7
Insults	11.6	12.0	52.7	56.5	29.8	48.1**
Spreading false rumours	2.4	6.3	17.5	21.0	56.7	69.2*
Nicknames	3.1	2.7	4.9	8.3	91.6	80.8
Negative criticisms	10.4	11.6	43.1	50.5	33.3	36.8
Ridiculing others	15.6	16.1	56.7	61.4	7.8	7.6
Hiding things	7.0	9.4	17.1	14.2	59.2	45.4**
Stealing or breaking things	12.2	8.7	19.6	16.7	43.1	44.8
Direct physical aggression	89.3	96.0	30.2	32.1	2.7	0.3
Intimidation	87.5	73.4***	9.6	21.3***	11.5	2.2***
Forcing others to do things against their will	86.2	79.8	3.3	2.9	1.4	0.7

* $p < .05$; ** $p < .01$ *** $p < .001$.

Gender differences are also found in the modality of indirect physical abuse, specifically in behaviour such as hiding personal items from others to ridicule them in front of peers. In this case, the dominant perception is the mechanism of social interaction, being much more relevant in boys than in girls ($p < .01$).

A final type of behaviour where gender differences were present is that of intimidating threats. The general perception is that of a behaviour which demonstrates the existence of an asymmetry of power between peers, although this perception is shared more by boys than by girls ($p < .001$). Similarly, the boys score higher on the criterion 'form of social interaction' ($p < .001$), considering this type of threat to be formulas for fun and cementing relationships which some young people use when they lack other social skills when interacting with peers. Girls, in contrast, often assigned a clear intention to cause harm to this type of intimidating behaviour ($p < .001$).

Identification of Aggressors, Victims, and Witnesses

Although the roles involved in a situation of school bullying are multiple, in this work we have only taken into account those of aggressor, victim and witness. The grouping of students into each of these types is made from the behaviour they claim to have followed in the example situations of abuse. The aggressor is considered to be the adolescent who admits abusing another classmate continuously, regardless of type of aggression committed. Similarly, a student who reports having been the receiver of some aggression on an ongoing basis, whether verbal, physical, or social, is considered a victim. Finally, the witnesses are students who state that they have been observers of continued episodes of aggression and have not tried to stop them.

The questionnaire design would also have permitted us to detect students playing more than one role. However, this was not considered in the present work, so that the sample was distributed as follows (Table 4):

The influence of the frequency of aggression on the perception of bullying was another of the variables analysed. This required those who for whom the abuse occurs 'Sometimes' and those for whom it is 'Always'. We binned the frequencies 'often' and 'always' into this latter category. The resulting distribution of the sample is presented in Table 5.

A more detailed analysis of the bullying situations registered shows, firstly, that the percentage of victims, aggressors and witnesses who suffer, commit or observe abuses that occur 'Sometimes' is far superior to in the category 'Always'.

Table 4. Distribution of the Sample According to the Role Played

		Gender		Total
		Boy	Girl	
Role played	Victim	173	183	356
	Aggressor	199	125	324
	Witness	758	685	1443
Total		1130	993	2123

Table 5. Distribution of the Sample According to the Role Played and frequency of aggression %

		Frequency	
		Sometimes	Always
	Victim	15.8	3.0
	Aggressor	15.5	2.1
	Witness	44.5	26.6

Secondly, the patterns of abuse with the highest percentages of aggressors, victims and witnesses are verbal attacks, both direct and indirect, followed by abuses related to social isolation. Thirdly, there are statistically significant differences between boys and girls. While boys scored higher in behaviour such as 'insults', 'nicknames', 'not letting participate', and direct or indirect physical aggression, girls stand out in indirect aggression such as 'spreading false rumours'. And fourthly, as the age of the students advances, direct physical and verbal abuses are replaced by indirect modalities such as 'spreading false stories' which seek to damage the other person's image, or behaviour intended to cause social exclusion.

The Aggressors' Perception of Bullying

The concept that aggressors have of bullying is based on the two criteria: 'imbalance of power' and 'intent to hurt', with the former predominating (.801) over the latter (.575). With this definition as referent, the results reveal that aggressors only consider direct physical aggressions such as fighting, pushing, and hitting as bullying (Table 6).

Table 6. The Aggressors' Perception of Bullying. Rotated Component Matrix

	Components		
	1	2	3
Definition of bullying		.575	.801

Forcing others to do things against their will			.913

Extraction method: principal component analysis.

Rotation method: Varimax.

The rotation converged in 3 iterations.

KMO = .68 α = .001.

It is particularly significant that the aggressors perceived 7 of the 12 forms of abuse included in this study as mechanisms of social interaction between peers. I.e., aggressors perceive behaviours that cause the social exclusion of a classmate, direct verbal abuse, and indirect physical abuse as normal forms of interactive behaviour.

The criterion 'intent to harm' only expressly appeared in one of the types of behaviour included in the modality of indirect verbal abuse – 'negative criticism' (.481).

Finally, both intimidating behaviour (.904) and behaviour seeking to force others to do things against their will (.913) are perceived as signs of obvious asymmetry of power that can only be carried out by those of a higher status. However, they do not attribute to these behaviours the 'intent to cause harm', and therefore do not classify them as possible examples of bullying.

The Victims' Perception of Bullying

The criterion that the victims use to define and identify violent behaviour as bullying is the 'intention to hurt' (.809). I.e., any violent behaviour in which the aggressor is perceived to have an intention to cause harm is considered an episode of bullying. These data indicate that the imbalance of power that was so notable in the aggressors' perception of bullying is of no relevance to the victims. Therefore, one can deduce that the victim does not necessarily see their aggressor as a physically or socially stronger person, but that both may have the same status. This perception of bullying is repeated in various forms of behaviour – social exclusion (.740), insults (.579), verbal abuse intending to ridicule the victim in the presence of peers (.788), and indirect physical abuse such as hiding or breaking personal items (.387). From the victims' standpoint therefore, all these types of behaviour are considered manifestations of bullying (Table 7).

Table 7. The Victims' Perception of Bullying. Rotated Component Matrix

	Components		
	1	2	3
Definition of bullying		.809	
Social isolation		.740	
Not letting the other participate in class	.311	.617

Forcing others to do things against their will			.736

Extraction method: principal component analysis.

Rotation method: Varimax.

The rotation converged in 4 iterations. KMO = .81 α = .001.

Moreover, the results presented in Table 7 show that the criterion 'intent to hurt' is present in a greater number of types of behaviour, although not exclusively but shared with other criteria such as power imbalance. This applies, for example, to the direct physical aggressions which are interpreted by victims as episodes of bullying whose manifestation is usually accompanied by a supremacy of power in favour of the aggressor. In some other modalities of behaviour (being boycotted in class, being given offensive nicknames, and receiving negative criticism), as well scoring the intentionality criterion, the victims also scored the 'form of social relationship' criterion. The explanation that can be attributed to this finding is that they do not always perceive 'intent to harm' in these types of behaviour, but that such a perception depends on the context and the moment that these types of aggression take place. It remains to be determined whether this duality of interpretations is motivated by differences in prior experiences of victimization, i.e., whether those who have already felt themselves abused with any of these types of behaviour perceive intentionality in them, while those who have never experienced them see them as patterns of social interaction.

Finally, intimidating forms of behaviour are not perceived as manifestations of bullying, but as signs of power that some students use to demonstrate superiority in their peer group.

The Witnesses' Perception of Bullying

Globally, the criteria that underpin the witnesses' definition of bullying the witnesses are 'intention to hurt' (.789) and 'power imbalance' (.433). The hierarchy of these two is contrary to what was observed in the case of aggressors, in which the relationships were reversed, with 'intention to cause harm' giving the value (.575), and 'power imbalance' (.801).

However, the analysis of this definition in each of the types of behaviour conforming the presence of bullying showed that these two criteria do not appear simultaneously (see Table 8).

The rotation converged in 2 iterations. KMO = .77 α = .001.

It is particularly noteworthy that behaviour related to social exclusion, direct and indirect verbal aggression, and indirect physical abuse is not even considered to be aggressive, even though it may cause another person harm. Witnesses perceive the forms of behaviour in these categories as seemingly harmless pranks and mechanisms used by adolescents in their interactions with their peers, and which facilitate their entry and permanence in a group.

The intent to hurt is only attributed to insults and negative criticism. In the former case, the resulting perception is that of behaviours which occur with an intention to cause harm (.435), but sometimes such intention is diluted, and the behaviour is justified as being the use of vocabulary typical of adolescents which permits them to identify themselves as members of a peer group (.398).

Moreover, it is noteworthy that the witnesses do not perceive any clear intent to hurt in direct physical aggressions. The students who witness this type of behaviour tend to interpret it as a sign of dominance and superiority over a weaker classmate that someone with more power uses to demonstrate their status in front of their peers (.674), without necessarily implying that there has to be an intention to harm the victim. A similar interpretation can be applied to threats, both those referring to intimidating behaviour (.737) and those to forcing another person to do things against their will (.800).

Gender Differences in the Perception of Bullying As a Function of the Role Played

When the role played is that of aggressor, there were statistically significant differences in the perception of spreading false rumours ($p < .001$), giving offensive nicknames ($p < .05$), ridiculing others in front of the peer group ($p < .05$), direct physical aggression ($p < .1$), and threats ($p < .01$).

In the case of the use of defamatory comments, 52.7% of the boys perceive them as behaviours that contain a playful element that adolescents use to facilitate interaction in the group. However, this perception is shared by only 39.3% of the girls who, more than the boys, see the use of such comments as having an intention to hurt other classmates socially and personally. Previous experiences of victimization are probably involved in this type of interpretation.

The allocation of offensive nicknames is conceived by most of the boys (80.4%) as a typical adolescent behaviour denoting proximity amongst peers, and therefore can not be considered as a manifestation of bullying. This perception is shared by two-thirds of the girl aggressors who, more than the boys, perceive this behaviour as involving the intention to cause harm (Table 9).

In relation to actions directed at ridiculing another in the presence of peers, the results show that a greater percentage of girls than boys ascribe intentionality to them and perceive power imbalance in the figure of the aggressor. By contrast, more boys than girls understand these types of behaviour to be forms of social interaction among adolescents.

Hitting, kicking and shoving are perceived as manifestations of bullying, although boys more than girls emphasize both the intent to hurt and the imbalance of power criteria.

Finally, the differences found in threats (both those involving intimidating behaviour and those seeking to compel another to do things against their will) are more focused on the supremacy of power of the aggressor (Table 9) in the case of the boys.

* $p < .05$ ** $p < .01$ *** $p < .001$.

When the role played is that of victim, gender differences are found in the conceptualization of bullying ($p < .05$). More girls than boys indicate the 'intent to harm' as an identifying criterion, while more boys than girls believe there must be an 'imbalance of power' between aggressor and victim for an aggressive behaviour to be considered bullying.

The remaining differences are related to different forms of verbal aggression. One is spreading false rumours ($p < .01$) which most boys conceive of as a means of social

relationships typical of adolescents, while most girls perceive as an aggressive act that seeks to harm the person who is the subject of such rumours (Table 10).

The assignment of offensive nicknames is another type of behaviour where there are gender differences ($p < .05$). In this case, although more than half of the students do not perceive this behaviour as a manifestation of bullying, 29.8% of the girls and 17.9% of the boys ascribe the 'intent to harm' to the person who uses nicknames to refer to a classmate.

The third type of behaviour in which there were gender differences among the victims is that of actions aimed at publicly ridiculing others ($p < .05$). More girls (82.7%) than boys (74.9%) see this behaviour as involving the 'intent to harm'. In contrast, more boys than girls perceive 'power imbalance' in the aggressor, and find it possible that these actions should be seen as pranks, not bullying.

Finally, when the role played is that of witness, again significant differences are found in the conceptualization of bullying ($p < .01$), with more girls than boys alluding to the 'intentionality' and 'imbalance' criteria. There are also significant differences in the modality of intimidating threats ($p < .001$) with boys tending to emphasize the presence of 'power imbalance' and the possibility of it being typical innocuous behaviour that occurs in interactions between adolescents. In contrast, girls tend to perceive these threats as behaviour that occurs with the intention to hurt and provoke fear. Finally, there are gender differences in insults ($p < .01$) and spreading false rumours ($p < .05$), with the girls tending to emphasize that these types of behaviour may in fact be simply playful, depending on the circumstances, the moment, or the people involved, rather than manifestations of bullying.

Differences in the Perception of Bullying as a Function of the 'Frequency of Aggression' and 'Role Played'

In the case of aggressors, significant differences were detected between those who say they show aggression 'Sometimes' and those who do so 'Always'.

First, it is observed that as the frequency of aggression increases, greater scores are reached acquired by the 'power imbalance' criterion, and notably lower scores by the 'intent to harm' criterion, regarding both the aggressors' conceptualization of bullying ($p < .01$) and the different modalities of aggression.

Second, those who abuse 'Sometimes' tend to see the behaviours that cause social exclusion, verbal abuse and indirect physical attacks as normal behaviour of adolescents facilitating their interaction with peers. In contrast, those who abuse 'Always' tend to ascribe the behaviour with 'intent to harm' or 'imbalance of power', but not with the combination of the two criteria (Table 11).

And third, there are major variations in the perception of the 'intent' and 'imbalance' criteria. While the 'Sometimes' aggressors only score in 'intent' on 2 of the 12 types of bullying behaviour included in this study, the 'Always' aggressors scored on 6 of them. The case is similar for the 'imbalance' criterion. While those who abuse 'Sometimes' only emphasize the asymmetry of power in 5 of the 12 aggressive behaviours considered, those who abuse 'Always' emphasize this asymmetry in 3 more types of behaviour – social exclusion, boycotting the victim's class participation, and the assignment of offensive nicknames ($p < .001$).

Sometimes: KMO = .69; Bartlett = .001. Always: KMO = .68, Bartlett = .001.

* $p < .05$; ** $p < .01$; *** $p < .001$.

Self-perception differences also extend to the students who play the role of victims. The results show that those who have been abused 'Sometimes' gave significantly lower scores to the criterion 'intent to hurt' than those who have been abused 'Always', both in their definition of bullying and in their identification of its modalities (Table 12).

Instead, the scores for in the criterion 'power imbalance' show that, as the frequency of aggression suffered rises, the emphasis given to the asymmetry of power lessens in direct physical aggression ($p < .05$), and in threatening and intimidating behaviours.

Another noteworthy difference is in the perception of bullying as a form of social interaction. The 'Sometimes' victims tend to justify more often and a wider range of aggressive behaviour as mechanisms that facilitate interaction between peers, and which, a priori, need not hurt another person. Only in the cases of 'assigning nicknames' ($p < .05$) and 'boycotting participation in class' ($p < .001$) do victims allow a two-fold interpretation – either as a pattern relating socially, or as abuse committed with the intent to hurt – with which of the two depending on the person, the moment, and the context in which the aggression occurs.

Finally, there was a marked change in the perceptions of spreading false rumours ($p < .01$), of negative criticism ($p < .001$), and of hiding or breaking personal items ($p < .01$), which are considered by the victims who suffer bullying 'Sometimes' as harmless acts that take place in peer groups to demonstrate membership in them, while victims who feel abused 'Always' perceive them as aggressive forms of behaviour that occur with the express intention of harming others.

Always: KMO = .74, Bartlett = .001.

* p<.05; ** p<.01; *** p<.001.

With regard to the third role, witnesses, the frequency of the aggression affected their perceptions of bullying. Those who 'Sometimes' were viewers of aggression scored the criterion of power imbalance significantly lower than did those who were witnesses 'Always' ($p < .01$).

Another difference is that those who are witnesses 'Sometimes' tend to perceive most of the forms of abuse listed in Table 13 more as forms of greeting, communication and interaction among peers rather than episodes of bullying than do those who are witnesses 'Always' (Table 13).

In contrast, the highest scores for the criterion 'intent' came from the witnesses who most often observed peer aggression involving verbal abuse and direct and indirect physical assaults.

Another differences is that the witnesses classified as 'Sometimes' do not perceive social isolation as aggressive behaviour, but those included in the 'Always' category explain that, for such exclusion to be carried out, there must be an imbalance of power in favour of the aggressor.

CONCLUSION

The search for more effective prevention and intervention programs to combat violence in school justifies the diversity of approaches adopted by current research on bullying. In our case, we wanted to approach the study of adolescents' perceptions of this phenomenon in general and of the various forms in which it can be present in the school context.

But the most important contributions of this work reside not only in the identification of the criteria that conform these perceptions, but also in the detailed analysis of the variability in the application of these criteria according to the student's gender, the role played in bullying situations, and the frequency of the aggression suffered, committed or observed.

In this regard, we must emphasize that the adolescents' perceptions of bullying are far removed from those assumed and defended by the scientific community. For adolescents, the recurrence of aggressive behaviour is not a defining criterion of bullying. And there are significant differences in the assumption of the 'power imbalance' and 'intent to harm' criteria between the different roles that the students might play in situations of aggression. The aggressors, probably due to the perception they have of being physically or psychologically more powerful, enjoying social approval and recognition from their peers (Schwarzwald, Koslowsky & Brody-Shamir, 2006), give greater importance to the asymmetry of power than to the intent to harm, although they consider both. This emphasis on the imbalance criterion is particularly evident in the aggressors who abuse other classmates 'Always'.

The witnesses, although also using both criteria to conceptualize bullying, put the accent on intent, and relegate power imbalance to the background. According to Gini, Pozzoli, Borghi & Franzoni (2008), the fear that witnesses feel of getting hurt themselves if they intervene to stop the aggression may be one of the arguments explaining the importance they attach to this criterion. This fear seems to be more present in the girl witnesses who are very often spectators of episodes of bullying.

Instead, the main criterion governing the perception that victims have of this phenomenon is that of 'intent to harm'. The experiences of aggression and the physical, psychological and social pain they have experienced influence the construction of this perception, which is especially acute in girl victims who suffer abuse 'Always'.

In relation to the conceptions that aggressors, victims and witnesses have of the different modalities in which bullying occurs, it is striking that many of the behaviours included in these modalities are considered as typical mechanisms of social interaction among adolescents. As indicated by Ojala & Nesdale (2004), membership in a peer group provides its members with a sense of social identity that not only describes them, but also prescribes their behaviour. For many adolescents, bullying may be considered acceptable as a process of social interaction when it is in line with group norms, and when directed at a person outside the group who represents a potential threat.

This equivalence established by the adolescents of bullying and a social interaction mechanism reflects the existence of maladjusted perceptions in the processes of interpersonal relations and moral balance (Twemlow & Sacco, 2008), and requires specific intervention measures for each case. The present results show that in the case of aggressors, as well as of the victims and witnesses, the scores on the 'form of social relationship' criterion increase significantly and cover more of the modalities of aggression considered when the attacks occur or are perceived with the 'Sometimes' frequency. Also, this trend is more marked in the boys than in the girls.

With respect to the types of abuse, those that are manifested orally, whether directly (insults, offensive nicknames) or indirectly (spreading rumours), through indirect physical abuse (hiding, stealing or breaking personal things), or leading to social exclusion (isolation, or not allowing the victim to participate in class), are those which both aggressors and witnesses generally tend to perceive as behaviour that promotes personal interaction among adolescents. Such seemingly peculiar interpretations from our standpoint as researchers lead us to believe that the adoption of these antisocial behaviours so as to interact with peers denotes a lack of social skills reflected in the assumption of unassertive models of getting on with other people in one's social context. These models are probably inherited from the family context or from a group of peers in the hope of obtaining some type of recognition or acceptance. As Menesini, Sanchez, Fonzi, Ortega, Costabile & Lo-Feud (2003) indicate, this is an imbalance in moral development which makes it hard for them to understand the seriousness of their actions and the damage they cause to others.

In the case of the victims, the types of abuse that they tend to perceive as patterns of social interaction are in most cases limited to spreading lies and indirect physical abuse such as hiding personal items from a classmate to ridicule them in public. Other forms of aggressive behaviour, such as 'not allowing them to participate in class', 'offensive nicknames' and 'negative criticism', are sometimes interpreted as mechanisms of social relationships and at other times as abuse with the intention of causing harm to another. Their previous experiences of victimization clearly condition victims' perceptions. One would need to know whether or not they themselves have repeatedly been the target of the forms of behaviour which they perceive as having the intent to hurt, and whether these occurrences have caused them great pain or continued distress.

If this greater depth of information were available, it would facilitate the adjustment of anti-bullying programs to match them to the realities of adolescents' perceptions, and thus optimize their effectiveness.

ABSTRACT

The social psychological factors that underpin choices to bully and sustain involvement in bullying have been relatively neglected in the research literature. This is somewhat puzzling since the extensive research conducted into bullying provides a strong indication that image, the need to dominate others in the course of establishing a hierarchy, and the establishment and maintenance of peer status, and social status in general, are important motivations for why young people bully others. These motivations are social group processes, and are very much aligned with the key elements of Reputation Enhancement Theory (RET), which has become a dominant theory in explaining why young people engage in delinquent and antisocial acts. RET is based on the premise that much child and adolescent behavior is motivated by the desire to present one's self to the peer community in a particular way and as a means to impress peers and gain their approval. Given that bullying occurs relatively more directly (overtly) than indirectly and predominantly in contexts where there is an audience present are indicators that RET may offer a plausible explanation for the underlying motivations for bullying.

In this chapter we demonstrate through the research literature, along with recently conducted studies, how the desire to attain a specific reputation of choice is a significant motivator for why individuals engage in bullying. We also examine why some bullies operate on their own rather than in a group, which is contra to RET. Finally, we show that the emergence of electronic technologies which provide for greater levels of invasiveness, reach a wider audience, and preserve anonymity on the part of the perpetrator (if they so wish to) has provided bullies with an additional medium through which to enhance and sustain their reputation of choice.

INTRODUCTION

Bullying is a complex, multidimensional phenomenon (Kyriakides, Kaloyirou, & Lindsay, 2006), which has serious, long-term mental health, well-being, and psychosocial consequences for perpetrators, victims, bystanders, and communities alike (Cross, Epstein, Hearn, Slee, Shaw, & Monks., 2011a; Cross, Monks, Hall, Shaw, Pintabona, Erceg et al. 2011b; Green, Collingwood, & Ross, 2010; Marsh, Nagengast, Morin, Parada et al., 2011; Nation, Vieno, Perkins, & Santinello, 2008; Parada, Craven, & Marsh, 2008; Smith, Pepler, & Rigby, 2004; Swearer, Espelage, Vaillancourt, & Hymel, 2010). Research demonstrates that involvement in bullying is consistently associated with delinquent behavior (Rigby, 2008), depression and criminality, (Kaltiala-Heino, Rimpela, Marttunen, Rimpela, & Rantanen, 1999), as well as suicidal ideation, loneliness, isolation and school refusal (see Hazler, Hoover, & Oliver, 1992; Kaltiala-Heino, Rimpela, Rantanen, & Rimpela, 2000; Nansel, Overpeck, Pilla, Ruan et al, 2001; Newman, Holden, & Delville, 2005; Woods & White, 2005). Consequently, bullying results in considerable socio-economic costs (see Green et al., 2010).

Bullying in schools has been a major focus of international research for some 25 years (see Andreou & Bonoti, 2010; Cheng, Chen, Ho, & Cheng, 2011; Nation, Vieno, Perkins, & Santinello, 2008; Rigby, 2008; Scheithauer, Hayer, Petermann, & Jugert, 2006) and rather than repeat the prevalence rates and definitions here, it is suffice to say that countries as diverse as Northern Ireland, England, Germany, the USA, Australia, Japan, Korea, and China have reported that up to 50% of school students claim to have been victims of bullying (e.g., Murray-Harvey, Slee, & Taki, 2010; Von Marees & Petermann, 2010; Koo, Kwak, & Smith, 2008; Wei, Johnson-Reid, & Tsao, 2007). The emergence of electronic technologies in recent years, particularly mobile phones and the Internet, along with the increasing penetration of networked computers has enhanced the potential for school aged students to engage in malevolent behavior (Shariff, 2008) and bullying (Smith, Mahdavi, Carvalho, Fisher, Russell, & Tippett, 2008).

While other contributors in this book will undoubtedly examine the prevalence of cyberbullying it is important to note for the purposes of this chapter that over 90% of school aged students in many parts of the world access the Internet, with 50% reporting daily usage (Cassidy, Jackson, & Brown, 2009; Popovic-Citic, Djuric, & Cvetkovic, 2011; Ybarra, Mitchell, Wolak, & Finkelhor, 2006; Yoon, Bauman, Choi, & Hutchinson, 2011). Why is this important? Basically because this wired culture in which contemporary adolescents operate (Kowalski & Limber, 2007) maximizes the potential of those who bully others to transcend real life and cross into the virtual world of communication (Popovic-Citic et al., 2011). In doing this, they reach a wider audience and achieve greater levels of invasiveness. Moreover, for those who want anonymity, they are able to preserve it (see Campbell, 2005; Kowalski & Limber, 2007; Pearce, Cross, Monks, Waters, & Falconer, 2011).

While much is known about the prevalence of bullying (and cyberbullying) and its consequences (see Scheithauer, Hayer, Petermann, & Jugert, 2006 for a review), it appears that the social psychological factors that underpin specific behavioral choices and sustain involvement in bullying have, in comparison, been relatively neglected (Von Marees & Petermann, 2010). There is no doubting that peers and the peer group are significant in the everyday lives of bullies, just as they are in the daily lives of young people who commit delinquent offences (see Carroll, Houghton, Durkin, & Hattie, 2009, for a review). According to Farrington (1993), the career paths perspective referred to in the delinquency research may

also explain trajectories to bullying. That is, a bullying career would be frequent over an extended time period. However, just as in trajectories to delinquency, only a small proportion of the population would engage in persistent bullying and this involvement might increase or decrease. A dominant theory which has emerged in explaining why children and adolescents become involved (and maintain their involvement) in delinquent behavior is Reputation Enhancement Theory (RET; Emler, 1984; Emler & Reicher, 1995) (for a comprehensive review see Carroll et al., 2009). Therefore, RET may offer a plausible explanation for the social psychological motivations underpinning the behavior of children and adolescents who bully others. Prior to examining bullying in the context of RET, however, it is necessary to provide a brief overview of the theory itself.

Reputation Enhancement Theory

RET (Emler, 1984) posits that individuals choose a reputation or social identity and then promote this before an audience of their peers. Individuals go to great lengths to both develop and maintain this reputation of choice (Emler, 1984; Emler & Reicher, 1995). The feedback received from the audience assists the individual to develop and maintain this reputation or social identity of choice within a relatively stable community of mutually acquainted and conversing individuals (Hopkins & Emler, 1990). To gain social visibility for reputational purposes there has to be direct witnessing of the acts by others, and/or self-disclosure through gossip and exchange of information (Carroll et al., 2009). Hopkins and Emler (1990) hypothesized that individuals communicate their reputations through intentional, visible behavior, primarily to persuade others that they belong to a particular social category. To acquire and maintain a delinquent reputation requires an audience who share a subculture (Gold & Petronio, 1980) and to ensure visibility, deviant/delinquent activities are not committed alone but in company (Reicher & Emler, 1986). Finally, as postulated by Reicher and Emler (1986), without the social support of a peer group a delinquent (or non delinquent) reputation is hard to sustain.

Therefore, an integral argument of RET is that individuals have public reputations and that this is the social goal of their conduct (Hopkins & Emler, 1990). Promoting a reputation is particularly important because of the credit it attributes to individuals within their social community (Emler, 1990; Emler & Reicher, 2005). Visibility of actions to others is therefore a key element on which the psychology of reputation has been built (Emler, 1984). Reicher and Emler (1986) made the point that the visibility of chronic rule breakers' conduct or the damage it will do to their reputations is not miscalculated; rather, they deliberately foster this reputation. Finally, reputation is a strategy of self-protection and redress for the individual and the group (Emler & Reicher, 1995). How then does RET explain the underpinning social psychological motivations for children and adolescents who bully others?

Reputation Enhancement Theory As a Social Psychological Motivation in Bullying

Bullying is a social group process (Gini, 2006; Woods & Wolke, 2004) whereby the relationship between the bully and the person(s) being bullied emanates from the dynamic

interactions which take place among a variety of variables which extend outside of the bully/bullied interactions to the whole group (see Menesini, Codecasa, Benelli, & Cowie, 2003). Research has demonstrated the crucial role peers and the peer group play in bullying (e.g., Atlas & Pepler, 1998; Craig, Pepler, & Atlas, 2000; Olweus, 2001; Rigby, 2005; Salmivalli, Lagerspetz, Bjorkqvist, Osterman, & Kaukiainen, 1996; Salmivalli & Voeten, 2004; Woods & Wolke, 2004). In line with this it has been hypothesized that bullies have a desire to be seen as strong, tough and powerful (Burns, Maycock, Cross, & Brown, 2008; Rodriguez, 2004) and that by satisfying their need to dominate others in the course of establishing a hierarchy (Pellegrini & Long, 2004), and establishing and enhancing peer status (Juvonen, Graham, & Schuster, 2003) they attain an image (Rigby, 2008). Bullying has also been explained by, among other things, group mechanisms and friends' expectations (Olweus, 2001; Rigby, 2005; Salmivalli & Voeten, 2004).

Thus, bullying meets the basic underlying social psychological motivation associated with RET, that is *the need to be seen by others in a specific way*. Support for this comes from what appears to be the first study specifically investigating reputation enhancement and choice among bullies. Nathan, Houghton, Tan, and Carroll (2011) administered the Reputation Enhancement Scale (Carroll, Houghton, Hattie, & Durkin, 1999) to 132 early adolescents (62 males [47%] and 70 females [53%]) from Grades 5 ($n = 27$), 6 ($n = 53$) and 7 ($n = 52$), 38 of who had official records of suspension from school for bullying peers. The ages of these participants ranged from 10.0 to 12.7 years (mean age = 11 years 4 months, $SD = 8.8$ months).

The Reputation Enhancement Scale (Carroll et al, 1999) comprises: a 32-item *social desirability scale* that examines admiration for law-abiding and law-breaking activities, the underlying value of reputation, and conformity or deviance to social attitudes; a 30-item *social identity scale* that measures participants' self-perception and how they would ideally like others to view them; a *self-identity scale* made up of two sets of 12 semantic differentials measuring how participants describe themselves and how they would ideally like to be described in terms of power (i.e., strong/weak, tough/soft) and activity (i.e., mean/kind, nasty/friendly) attributes; and a 56-item *communication of events scale* that measures patterns of disclosure of events to adults and/or peers, by participants.

A multivariate analysis of variance revealed that the bullies sought reputations that were significantly more nonconforming compared to non bullies and that this was how they wanted peers to perceive them. These bullies openly admired peers of their age involved in nonconforming activities; believed that other early adolescents of their age would have the same admiration for these individuals; believed that peers saw them (i.e., bullies) as someone who breaks rules, breaks the law, is a trouble maker, a bully, and tough; and they wanted others to perceive them in this manner. Previous research has also found that bullying among primary school aged children is an antecedent to achieving goals (O'Connell, Pepler, & Craig, 1999; Saufler & Gagne, 2000) and that bullies believe that everyone who behaves aggressively to others does so deliberately for a purpose (Dodge, 1991; Loeber & Coie, 2001). What the Nathan et al. (2011) findings seem to confirm is that bullying is a deliberate choice and that bullies are highly successful in their drive to get others to attribute them with specific characteristics associated with being strong, powerful and able to control others, just as Rigby's (1996) earlier research suggested. Further, indirect evidence supportive of this comes from Buelga, Musitu, Murgui and Pons (2008) who found that Spanish adolescents used aggressive behaviors as a

strategy to achieve power and status within the peer group and also as a means to satisfy certain needs involving social approval.

In a recent qualitative based study, Houghton, Nathan, and Taylor (2012) further investigated the construct of reputation as an underlying social psychological motivation in bullying by interviewing 28 (18 males and 10 females, aged 10 to 13 years) early adolescent school bullies. Official school records showed a repetitive pattern of bullying among these young persons, all of whom had clear opinions about their bullying of others. For example, bullying was a choice for them:

Bullies feel stronger and tougher than everybody. They want to be on top. Like all the kids never respected them so they have to fight and bash people to get that respect (Male, Grade 5)

I wanted to be on top, so I fight with people to get respect. I mean getting respect ...that's what it's all about (Male, Grade 6)

Furthermore, the nonconforming image that the bullies sought was not only achieved, but also reinforced by others:

Everyone tells me I'm bad - the other kids tell me. The teacher always tells me I'm a bad person, that I don't have any good in me. My parents tell me that I am bad at home and that no-one likes me and I am mean to everyone. Being bad gets me anything I want. So I feel pretty good about being bad (Male, Grade 7)

Attaining peer status has been highlighted by other researchers as a significant motivation for involvement in bullying (e.g., Juvonen, Graham, & Schuster, 2003; Kaltiala-Heino et al., 2000) and the early adolescent bullies interviewed by Houghton et al. (2012) provide strong support for this assertion.

The question remains, however, is how do bullies ensure that others see them in a specific way? In answer to this question, bullies choose to further cultivate their image of choice using a number of social psychological mechanisms that are key elements of RET. Moreover, the activation of these mechanisms further strengthens our contention that the image and reputation that bullies seek is a deliberate choice on their part and that they go to great lengths in the choices they make to maximise any opportunities to achieve this reputation. For example, bullying occurs relatively more directly (overtly) than indirectly (Nabuzoka, Ronning, & Handegard, 2009) and predominantly in contexts where there is an audience present (Astor, Meyer, & Pitner, 2001; Gini, 2006), or where children interact in unstructured contexts (e.g., during recess and in outdoor play: Gini, 2006; lunch times, extra-curricular events, and on the way to/from school: Isernhagen & Harris, 2002; and in school hallways, on school buses, and cafeterias: Astor, Meyer, & Pitner, 2001). Rigby (2008) made the point that bullies are not ashamed of what they are doing and want attention and an audience of peers to impress. Moreover, Gamliel, Hoover, Daughtry, and Imbra (2003) argued that bullies actually use the audience as a "theater" to their advantage. The following comment made by a male bully in the Houghton et al. (2012) study is typical of both boys and girls who bully in this regard:

I choose my place carefully. I mean why get somebody if no one is going to see you do it. You get nothing from that. When others do see you it makes you feel great because they know not to mess with you. You got to mean it (Male, Grade 6)

Thus, the *presence of others* in addition to the bully/bullies and victim(s) in a social context (e.g., bystanders) is particularly salient given the findings demonstrating that bullying is a relationship problem (Pepler et al., 2008; Scholte, Sentse, & Granic, 2010). According to Oh and Hazler (2009), bystanders are the most overlooked group even though their roles are critical in encouraging or reducing bullying behaviors (see Swearer et al., 2010). Observational studies conducted while children freely interacted during recess and in outdoor play, have confirmed the crucial role of peers in bullying by consistently noting peer involvement in 85% of bullying episodes (Atlas & Pepler, 1998; Craig, Pepler, & Atlas, 2000). Other studies have also revealed the strong influence of group behavior and/or the influence of the peer group or network on children's bullying (Cairns & Cairns, 1994; Salmivalli et al., 1997; Woods & Wolke, 2004). Thus, through their intentional, visible behavior bullies achieve a public reputation, which is the social goal of their conduct (see Hopkins & Emler, 1990). Furthermore, through involvement in bullying they create a certain (tough) reputation which persuades others that they belong to a particular social category (Emler & Reicher, 1995).

According to Pronk and Zimmer-Gembeck (2010) aggressive behavior is viewed as a means of maintaining/increasing status and striving for social dominance. The findings from a large scale quantitative study of early and mid adolescent boys and girls ($n = 455$, mean age = 12.5 years) that found gaining social power and group status were the primary motives in peer victimization, are supportive of this (see Gini, 2006). Moreover, according to Gini (2006, p. 62) young people attempt to raise their social status to enhance their own standing and gain dominance over peers and as such "viewed aggressive behavior towards weaker peers as an effective way to achieve social power". Hawley and Vaughn (2003) referred to this as the bright side to bad behavior. This latter assertion is supported by all of the male and female bullies interviewed by Houghton et al. (2012) who reported that the kudos they received by ensuring that peers witnessed their daring and brutality in high visibility locations helped them to gain widespread peer recognition for being "*hard*" and "*bad-assed*".

Thus, *visibility of actions* to others is another key social psychological motivating element on which the psychology of reputation is built. In the case of both boys and (particularly) girls who bully others, engaging in covert types of bullying such as writing comments on toilet walls is another frequently used strategy in addition to the more direct actions of physical bullying. According to the female bullies in the Houghton et al. (2012) study, using covert techniques such as writing on toilet walls reached a wider audience for the purposes of enhancing their reputations:

Everyone has to head for the toilets at some time so it's a good place to leave things. I wrote S is a filthy slut and P can't be trusted so don't tell her things. I mean, writing nasty things on the toilet walls and doors about someone - its easy and it works (Female, Grade 6)

In the case of male bullies in the Houghton et al. (2012) study, they go further than the females to ensure the visibility of their actions. To achieve high visibility they actively seek out the homes of their victims and then, more often than not during the evenings, commit additional group based bullying-related acts which involve deliberately damaging personal items such as

mail boxes, flower beds and trees. Male bullies believe that the victim soon associates this property damage with them (i.e., the bully group or an individual) which in turn creates more fear in their victims. Showing victims that the clutches of the bully extends beyond school permeates an even greater sense of fear. In many cases, when the parents of the victim or even the police visit the school to complain, this further increases the visibility of the bully and the bullying. How is this achieved? Quite simply, through the peer communication network, via which word spreads about the behavior of the bully(ies) and that they had stood up to persons in authority (i.e., teachers and police) by denying they had committed any such acts. As one male bully stated:

A is smart. He visits houses late at night. He has kicked down mail boxes, thrown eggs at people's windows and doors and he doesn't care. When C's parents complained to the school he just told them it wasn't him, even though every one of us all knew he had done it. C was pretty worried for sure. You could see it on his face (Male, Grade 7)

Rigby (2008) and Pellegrini (2004) found that bullies engaged in bullying to show how tough they were, and the out of school bullying behaviors described above seem to further reinforce the toughness that bullies strive to attain. Furthermore, since much of this after school bullying occurs in a social group context, it provides members with a sense of social identity and this not only describes them, but also prescribes their behaviors (Ojala & Nesdale, 2004). The standing up to authority and subsequent enhancing of reputations may be what attracts members (i.e., the appeal of associating with winners) to bullies' groups, as suggested by Estell, Farmer, and Cairns (2007).

Thus, in line with the social psychological motivations of RET, bullies provide public proof of character to others (see Goffman, 1972) by ensuring that their activities (either direct physical bullying or indirect covert bullying) are committed in company or are witnessed by others (Reicher & Emler, 1986). As RET proposes, without the social backdrop of a peer group, a nonconforming reputation is hard to sustain (Reicher & Emler, 1986).

Reputation Enhancement Theory and Those Who Bully Alone

Although the importance of the peer group cannot be underestimated, because without its (i.e., peer group) social support a nonconforming reputation is hard to sustain (Reicher & Emler, 1986), it is known that some bullies are social isolates with limited, if any friends (see Boulton & Smith, 1994; Vaillancourt et al., 2003) and operate successfully without the social support of a group. Individuals with none or very limited friendships have been classified as "loners" by some researchers (Demuth, 2004) and as "social isolates" by others (e.g., Adler & Adler, 1996). Irrespective of the name used, a common issue appears to be their limited friendship patterns (Demuth, 2004). Data from the National Longitudinal Study of Adolescent Health (see Kreager, 2004) demonstrates that social isolates who report having significant trouble with others ('peer trouble isolates') are more likely to become involved in antisocial activities and to form delinquent peer associations than isolates who report having little trouble with others ('invisible isolates'). Although there is research pointing to bullies as social and popular members of peer groups, there is also research suggesting that some are social isolates with limited, if any friends (see Boulton & Smith, 1994; Vaillancourt et al., 2003). In Australia,

Sakellariou (2005) found that although group bullying occurred more frequently than individual bullying, there was a small core group of approximately 2.5% of students who engaged in bullying on their own “several times a week”, while 4.1% did so “once a week”.

To date, there appears to be limited information on this group of social isolates and so little is known about the social psychological motivations underlying their bullying of others. Research with loner delinquents (10-18 years of age) has shown that they strive for nonconformity but desire this to be of a private nature, which is why they commit their delinquent activities without the presence of an immediate audience (Houghton, Carroll, Tan, & Hopkins, 2008). Following Farrington’s (1993) contention that the career paths perspective referred to in the delinquency research may also explain trajectories to bullying, Nathan (2010) applied RET to a small group ($n = 11$) of bullies identified as loners. The findings were clear in that the motivation to achieve nonconformity among peers was the priority. However, social conformity also figured prominently among these loner bullies, suggesting that a degree of confusion prevailed regarding their desired reputation of choice. Nathan (2010) concluded that bullies with limited or no friends (i.e., loners) may be in a state of transition along the delinquency/bully trajectory and therefore more malleable to intervention.

Is Reputation Enhancement Theory a Social Psychological Motivation in Cyberbullying?

Cyberbullying has been briefly defined as “sending or posting harmful or cruel text or images using the Internet or other digital communication devices” (Willard, 2003, p. 1). More recent definitions have been more comprehensive. For example, Shariff and Strong-Wilson (2005; cited in Shariff, 2008, p. 30) defined cyberbullying as comprising “covert psychological bullying, conveyed through the electronic media such as cell phones, weblogs and web sites, online chat rooms, MUD rooms (Multi User Domains where individuals take on different characters) and Xangas (on line personal profiles where some adolescents create lists of people they do not like)”. Smith et al. (2008) highlighted that cyberbullying is the intentional use of electronic forms of contact repeatedly and over time against a victim who cannot easily defend him or herself. Irrespective of any definition invoked, there appears to be little doubt among researchers and educators alike, that bullying has “gone digital” (Li, 2005, p. 271). Indeed, Smith et al. (2008) highlighted the “increasing penetration of networked computers” (p. 376) and the emergence of electronic technologies, particularly mobile phones and the Internet, as increasing the potential for bullying.

Thus, in line with RET, the use of these electronic technologies has the potential to achieve a wider audience (see Donchi & Moore, 2004; Smith et al., 2008) and although the perpetrator is less likely to receive direct gratification, (a key element postulated by RET - because he/she cannot see the victim’s direct response), they may receive social prestige because they share the abusive information or video clips with a wider audience (Smith et al., 2008). The earlier findings from the first Youth Internet Safety Survey (see Ybarra, Mitchell, Wolak, & Finkelhor, 2006) which indicated that around 50% of abusive information cyberbullying victims received is also posted or sent to someone else, supports the argument regarding reaching a wider audience.

In summary, cyberbullying is a mechanism through which young people can bully others and in doing so attain and enhance a reputation that they have chosen to pursue. That there is

growing evidence from research studies worldwide showing trends for cyberbullying as being between 6% and 33% and between 10% and 42% for victimization (see Campbell, 2005; Charlton, Panting, & Hannan, 2002; Hinduja & Patchin, 2008; Kowalski & Limber, 2007; Kraft, 2006; Mathews, 2004; Noret & Rivers, 2006; Oliver & Candappa, 2003; Slonje & Smith, 2008; Smith et al., 2008; Ybarra & Mitchell, 2004) suggests that some young people may already be adding electronic technologies to their bullying armoury. Whether cyberbullying is aligned to RET as an underlying social psychological mechanism has so far not been investigated.

In what appears to be the only study to date that has specifically investigated cyberbullying and RET, Houghton et al. (2012) interviewed 28 (18 males and 10 females, aged 10 to 13 years) school bullies with official school records of suspension for their repetitive patterns of bullying. What was striking was that many more of the female bullies than the male bullies used electronic technologies for bullying and the main reason given for this was clearly reputational based. According to the females, the technologies allowed them to reach a wider audience and the fact that it was in a delayed manner was especially important to them - even more important than reaching an immediate audience through direct physical bullying. The females reported they particularly favored the school Internet because it allowed them to make sure everyone knew *"what's going to happen to someone"*. This is not to say that other media was not used. For some females, the ability to be able to modify the content of, or replace another person's Facebook information or blog was fulfilling in their quest for a reputation:

S is one of the best at this. She changed somebody's details so it read like that she was a slapper; she is always calling others sluts and bitches. We all read it and laugh (Female, Grade 7)

Although on the surface it appears that cyberbullying may be primarily a female mechanism for the purposes of reputation enhancement, both the male and female bullies in the Houghton et al. (2012) study reported using electronic technologies. However, one of the main reasons for its use was for maintaining, rather than initiating, reputations of choice. In this scenario the goal was to create in the victim a sense of trepidation along with feelings of not being sure of whether the bully had in fact carried out the actions. This sinister behavior was not only reinforcing to the bully, but it was also inspiring within the peer group. As one male bully and one female bully, respectively confided:

Sending texts and emails means you can carry on to whoever you like after hitting them or scaring them. Texting can be done anytime but I like sending them really late at night so when they switch their mobiles on next morning the message is waiting for them. It's real fun waiting next day just to see how they act when they see you. You can tell they're scared (Male, Grade 7)

I can be real mean and bitchy after sending a message. I just pretend everything is OK for like two or three days. Then when she thinks everything seems normal I hold my phone up to the person and wave it about with a smile on my face. You should see the look on her face (Female, Grade 6)

Thus, it appears that cyberbullying is a social psychological mechanism through which bullies can extend their bullying repertoire and in doing so induce even greater levels of fear

and insecurity in their victims. The anonymity that goes hand in hand with cyberbullying (see Harmon, 2004) creates a hostile and suspicious physical environment, which Shariff and Strong-Wilson (2005) highlighted as an important mechanism in the context of cyberbullying. However, in the case of bullies, it appears that they only wish to preserve their anonymity for a temporary period because they subsequently invoke subtle mechanisms of communicating their intentions to their victims. This may include, for example, holding up a mobile phone and slowly and gleefully waving it from side to side, so as to show that it was they who sent the threatening text message or video. Thus, it is argued here that bullies do get immediate gratification from their initial anonymity because they know that after a short time they can reveal themselves to their victims. Moreover, the delayed gratification they subsequently receive is additionally reinforcing, which in many ways is an extension to current RET. Thus, in line with RET bullies utilise the social psychological mechanisms of the electronic media to attain a nonconforming reputation of choice and they go to great lengths, such as delaying revealing their identity, in order to promote this reputation before an audience of their peers (Emler, 1984; Emler & Reicher, 1995).

In summary, the review of research presented in this chapter provides strong support for RET (Emler, 1984) as a plausible predictive social psychological mechanism underpinning school aged students bullying of others. How can it all be summarised in the context of the bullying of others? Irrespective of whether the bullying is direct or indirect or involves the use of electronic media, those who bully others are motivated by the desire to present one's self to the peer community in a particular way (Emler & Reicher, 1995) in order to impress peers and gain their approval (Agnew, 1991). This is the case irrespective of gender, although girls tend to employ more indirect methods of bullying, which is in line with previous research findings (e.g., Kyriakides, Kaloyirou, & Lindsay, 2006; Sakellariou, 2005). What is also clear is that the feelings of strength and power, and the resulting recognition that emanates from bullying provides the status that bullies deliberately set out to achieve (Juvonen et al., 2003; Kaltiala-Heino et al., 2000; Rigby, 1996). Moreover, they choose their location to bully with great care so as to promote their self-image before an audience of their peers. In line with RET this audience then provides feedback so that the individual develops and maintains this social identity within a community. Indeed, there appears to be a familiar cyclical nature to reputation enhancement and bullies which is similar to that of young offenders and at risk youth (see Carroll et al., 2009). That is, bullies commit acts of bullying, sometimes in a proactive manner, in highly visible locations to impress others. The bullies themselves ensure their behaviors are publicized by subsequently bragging to others, while their victims further the cause by also telling others (students and teachers); this is in addition to the direct witnessing by onlookers, who also then communicate the acts of bullying to others. Thus, the communication of events is very well developed in the construct of bullying and this undoubtedly serves to enhance the reputation of the bully.

It should also be recognised that there are some young people who bully others but who do not seem to fit with the summary presented above. These are individuals in every sense of the word, in that they bully others but not in the company of peers. Nevertheless, these loner bullies, like their more peer group oriented bullies, still see themselves as nonconforming, believe that others view them in this way, and desire to be seen in this way. Thus, irrespective of bullying with or without the company of others, having a reputation is still the social psychological goal of their conduct, as posited by Hopkins and Emler (1990). Thus RET is a plausible explanation for those who indulge in bullying on their own.

Implications for Education

There can be little doubt that reputation is a significant underlying social psychological mechanism that motivates some young people to become involved in bullying others. Therefore, developing a clearer understanding of bullying and the significance of RET is important because of the potential benefits for the prevention of such behavior during the school years and beyond. Carroll and colleagues (see Carroll et al., 2009) have clearly demonstrated the significance of reputation in explaining why young people indulge in antisocial and delinquent behaviors. This present review has juxtaposed the findings from Carroll and colleagues and others such as Emler and Reicher in the field of RET, with the research on bullying. In doing so, support has been provided about the importance of RET as a predictor of bullying, and thus its necessary inclusion in what Rigby (2008) termed as research-led best practice. Further support for this comes from Buelga et al. (2008, p. 198) who argued that “the construction and management of reputation should be included in programs of prevention of violent behavior in the school setting, as this is undoubtedly a very important variable in the life of adolescents”.

The question is how can the management of reputation be included in programs? Indeed, without great care it may actually be counter-productive. For example, to modify the reputations that bullies go to great lengths to attain, or to prevent the development of a nonconforming reputation in the first place, educators need to focus their efforts on the bullies and the intentional, visible behavior that they (the bullies) deliberately propagate to cultivate their nonconforming reputation. However, this in itself is the goal of bullies and therefore the efforts and attention of educators may inadvertently generate the reputation the bully seeks. How then can schools reduce the visibility of the bully and his/her behavior without drawing attention to it? We argue that there are a series of steps that schools can take.

It is crucial that educators and system administrators understand that bullying is a relationship problem whereby those who bully are learning to use power and aggression to control and distress others. It goes to say that they must therefore understand that relationship problems require relationship solutions (Pepler, 2006) and perhaps one of the first things that should be undertaken is to ensure that any interventions that are introduced in schools identifies the needs of those who bully (in terms of relationship skills) and then supports and enhances their relationship capacity to promote healthy relationships (Pepler, 2006).

The central role of peers in promoting the dynamics of bullying (see Craig & Pepler, 1997) highlights the importance of maximizing any opportunities to structure children's peer groups to promote positive peer experiences and deconstruct negative peer experiences (i.e., social architecture) (Hawkins, Pepler, & Craig, 2001; Pepler, 2006). In doing this, those who bully may become more involved in prosocial activities that enhance conforming, rather than nonconforming reputations. In addition, the influence of the peer group in terms of providing feedback to those who bully must also be acknowledged in relation to interventions. In line with this we suggest that multimedia based interventions which remove the immediate presence of an audience may offer great potential for preventing students' progression along the trajectory towards greater involvement in bullying. Without the social backdrop of a peer group, a non-conforming reputation is hard to sustain (Reicher & Emler, 1986). (We expand on this subsequently.)

Nabuzoka et al. (2009) drew attention to the potential of bullying to adversely affect the general school atmosphere and so it is important strategies are developed that reduce the visibility of bullies and their actions, particularly by reorganizing student's group structures so

that negative leadership through bullying can be transformed to positive leadership within the school context (see Pepler, 2006). In doing so the opportunities to achieve and enhance a desired nonconforming reputation may be diminished. It may also be at this time that schools employ programs which teach bullies *how* to attain reputations which are conforming rather than nonconforming, and which are achieved through participation in more prosocial activities, yet still result in enhanced status among peers. In line with Burns et al. (2008), we would emphasize that schools must acknowledge the strength and influence of the peer group and the need for peers to conform as being paramount to the development of appropriate intervention strategies.

To address the critical need to reduce visibility while still allowing bullies (or those on the trajectory to bullying) to attain a reputation is difficult, especially given the advent of cyberbullying. Cross et al. (2011a, 2011b) drew attention to the finding that the prevalence of bullying has remained largely unchanged despite the multitude of interventions claiming to be effective. Therefore, we argue that interactive multimedia-based interventions should be initiated within schools. Indeed, the increasing use of multimedia technology among school students, along with the opportunities such technology provides to include motivational, attitudinal, and skills-training components (which have better empirical support than educational approaches: Larimer & Crouse, 2002; Walters & Bennett, 2000) makes it highly advantageous (Walters, Miller, & Chiauzzi, 2005). In the context of school bullying, an individualized multimedia intervention, set in a classroom based regular lesson, would remove (or reduce) the immediate presence of an audience and therefore the visibility that those who bully others so desperately need. To reiterate, as Reicher and Emler (1986) contended - without the social backdrop of a peer group, a nonconforming reputation is hard to sustain. Inextricably linked to this latter point, interactive multimedia-based interventions may also reduce the likelihood that bullies will be grouped together in one program setting. In doing so it reduces the potential to create the reputation of choice and for the bully to behave in ways consistent with the label of bully.

In conclusion this present review has shown that reputation enhancement is an important social psychological motivating mechanism underpinning bullying. School aged students decide how they wish to present themselves to others and count the costs of this by gauging the reactions they get (Emler, 1984). Furthermore, the socially attractive aspects associated with bullying and the importance assigned to the peer group that bullies associate with appears greater than any possible negative or detrimental outcomes. Therefore, bullying needs to be understood in relation to the social purposes it serves and the goals that are met by undertaking it. Only by achieving this might intervention programs be developed that change the social identities of young people who bully for the better and break involvement in, or the trajectory towards, greater levels and intensities of bullying.

Stephen John Houghton, PhD, is director of the Centre for Child and Adolescent Related Disorders. His area of research is child and adolescent developmental psychopathology, with a particular focus on Attention Deficit Disorders, conduct disorder and the construct of juvenile psychopathy.

Annemaree Carroll is Associate Professor in the School of Education at The University of Queensland. Her research focuses on the psychological determinants of adolescents who are at-risk of engaging in delinquency, substance abuse, aggressive behaviors, and bullying.

Carol Tan is an academic at Nanyang Technological University in Singapore, where her research interests include delinquency, juvenile psychopathy, and the peer friendship and social networks of children and adolescents.

Elijah Nathan, PhD, researches and works with early adolescents in the area of bullying. He has developed and delivered school-based bullying programs to schools throughout Western Australia.

Chapter 97

THE ROLE OF FATHER INVOLVEMENT IN CHILDREN'S BULLYING BEHAVIOR: AN OVERVIEW OF THE LITERATURE

Theodoros Giovazolias* and Olga Themeli

Assistant Professor in Counseling Psychology
Department of Psychology, School of Social Sciences
University of Crete

ABSTRACT

It has been argued in the literature that fathers and mothers may play distinct and complimentary roles in parenting and that they interact in different ways with their children. Recent studies have found that children's perception of fathers' parenting style influence children more strongly than did their perception of mothers' parenting style. Further, effects of father involvement and support have been shown to be associated with positive child outcomes in different areas of their psychological adjustment. However, little is known regarding the effects of father parenting in the prevalence of bullying behavior in children. The aim of this review article was to summarize the key trends in the research of the role of paternal involvement in children with regards to their psychological adjustment and their participation in bullying incidents. The implications of the issues raised from this literature review for counseling interventions are also discussed.

Keywords: Parenting, father involvement, bullying, victimization

DESCRIPTION OF BULLYING

Bullying is an international phenomenon affecting a large number of students worldwide, from the United States to Japan (Eslea et al., 2003). Despite the magnitude of this phenomenon and the short- and long-term impact that may have to all those involved, it was not until the

* Corresponding Author's Email: giovazot@uoc.gr

1980s that bullying became an object of systematic study and research (Olweus, 1993). Victimization/bullying involves repeated, long term negative actions (intentional infliction of injury or discomfort) from one or more students against another student (Olweus 1993, 1994).

Researchers have pointed out that it consists of a conscious and deliberate behavior on behalf of the perpetrator who exerts some sort of power over the victim (Johnstone, 1991). In the opposite case, where two students of equal power enter a clash situation, it is no longer classified as bullying but as conflict (Olweus, 1993).

For a more complete definition of the term “bullying”, its 5 major points are presented, as described by Greene (2000).

Research data from all continents show that a significant number of students in all school grades participate in one way or another in incidents of aggressive insults and victimization (Fekkes, Pipers, & Verloove-Vanhorick, 2004; Hawker & Boulton, 2000; Sullivan, 2000). The exact incidence of this phenomenon is difficult to determine, and varies depending on the country and the age of the students.

Research in the Scandinavian countries have shown that the incidence of bullying varies between 10 % and 15% (Olweus, 1994; Olweus, 1997). Specifically, in a relevant study it was shown that 9% of students, aged 8-16 were victims, 7% were engaging in bullying behavior, and 1.6% belonged to the bully/victim category (Olweus, 1993). In a study involving a sample of 5.000 students of Swedish schools, it was revealed that 11.1% of boys and 9.1% of girls were facing bullying behavior 2 or 3 times every month (Solberg & Olweus, 2003).

In Britain, the incidence of bullying is much more widespread. According to research data, about 18-20% of students have reported some kind of bullying involvement (Boulton, & Smith, 1994; Boulton & Underwood, 1992). In a sample of 6.700 students aged 8-16 years, it was found that 27% of elementary school students were victims at least sometimes during the last trimester, with the percentage decreasing to 10% for secondary education students. Concerning the bullies, the percentages were 12% and 6%, respectively (Whitney & Smith, 1993). In Ireland, 13% of elementary school students, and 5% of middle school students had faced bullying behavior, at least at some point during the last trimester (O’ Moore, 2000).

Research data show that in Greece the incidence of victimization is – on average – the same as in other European countries. In a recent research by Giovazolias, Kourkoutas, Mitsopoulou, and Georgiadi (2010) it was found that in a sample of 371 elementary school children, 16.2% were victims, 2.7% were bullies and 7.8% belonged to the bully/victim group. In another study by the General Secretariat for Youth, 29.4% of a teenage sample reported that they had been exposed to various forms of bullying by other children (Psalti, Papathanassiou, Konstantinou, & Deliyanni, 2005). Therefore, it seems that victimization is a universal phenomenon, which

can take place in almost all schoolrooms, as well as in schoolyards, and demands intense research and treatment.

In order to distinguish more easily between the different types of bullying, we distinguish two types of victimization, direct and indirect bullying.

Bullying can take two main forms; *direct bullying* is characterized by a direct assault on the victim, and usually involves physical contact (i.e., punching, kicking). In *indirect bullying*, the perpetrator is not physically engaged in the assault. Most likely, he/she is encouraging others towards the victim; this type of bullying may be more verbal (e.g., swearing, nicknames, etc.) and/or non-verbal (e.g., staring intently at someone). Indirect bullying may also be psychological in nature (i.e., exclusion of some students from activities, spreading of rumors, blackmail, etc.). In summarizing, direct bullying is manifested through relatively open attacks against the victim, while indirect bullying is mostly manifested through social isolation (Rigby, 2008; Salmivalli, Lagerspetz, Osterman, & Kaukiainen, 1996). Other forms of bullying include cyberbullying, racial bullying, and sexual bullying. According to the research data of the last decades (Card, Stucky, Sawalani, & Little, 2008; O'Moore, 2000; Pateraki & Houndoumadi, 2001; Sapouna, 2008; Whitney & Smith, 1993), boys tend to get involved mostly in direct types of bullying, while girls in more indirect forms (e.g., spreading rumors).

CONSEQUENCES OF BULLYING

Numerous researches focus on the consequences of victimization by peers, as well as on the personality characteristics and the problems faced by bullies, victims, and bullies-victims. All researches agree in that bullying pose a serious problem at an international level in all schools, which affects the mental health of a large number of victims, leading to serious psychological, behavioral, and academic problems (Nansel, Craig, Overpeck, Saluja, & Ruan, 2004; Totura, Green, Karver, & Gesten, 2009). More specifically, it has been found that victimization relates to internalizing problems such as anxiety, depression, feelings of loneliness and low self-esteem (Hawker & Boulton, 2000). Further, the experience of bullying behaviors has been associated to different emotional states, such as anger, guilt, confusion, and the intense sadness experienced by the victim (James, Sofroniou, & Lawlor, 2003; Luis, 2004). Furthermore, victimization is also associated with more serious and long-lasting effects, such as somatoform disorders, physical health problems, antisocial behavior, self-injuries, suicide attempts, sleep problems (insomnia), and Attention Deficit Disorders- Hyperactivity (Dyer & Teggart, 2007; Ireland, 2005; Kumpulainen, Rasanen & Puura, 2001; Mills, Guerin, Daly, Lynch, & Fitzpatrick, 2004). In a relevant study, it was found that experiencing victimization from peers of the same age directly contributes to the development of emotional problems and to the development of poor social relationships (Bond, Carlin, Thomas, Rubin, & Patton, 2001).

However, it seems that bullies also experience problems. Specifically, they tend to be more aggressive compared to other students, and they are more likely to utilize force in order to react to their anger (Espelage, Bosworth, & Simon, 2000). It has been also suggested that when compared to uninvolved students, they have more incidents of depression (Nansel et al., 2001). Bullying is also related to incidents of violent and dangerous behavior, such as frequent injuries because of fighting, and possession of handguns (Nansel et al., 2001). It has also been related to the appearance of behavioral problems, such as hyperactivity, problems in organizing and

executing activities, and difficulties in their interpersonal relationships (Juvonen, Nishina, & Graham, 2000). It has been noted that children engaging in bullying behaviors are extremely aggressive and possess the ability to manipulate other children, so that they can exert control over them (Totura, et al., 2009). Furthermore, concerning their academic performance, it has been found that they display poor academic performance in school, and spend less time with their homework, regardless of their mental capacity (Graham, Bellmore, & Mize, 2006).

THE RELATIONSHIP BETWEEN PARENTAL BEHAVIOR AND BULLYING/VICTIMIZATION

The contribution of family dynamics to the development and display of problematic behaviors in childhood and adolescence has been one of the most important parameters in the research on aggression and deviant behavior during the last decades (see Campbell, 2002). Overall, it is suggested that family dynamics (structure, organization, emotional climate, communication etc.), the standards of relationships/attachment, and the interpersonal and systematic interactions, seem to define to a large extent the behavior and the relation of the child to others, to the extent that the child adopts, internalizes and develops standards of behavior and conciliation with the others, based on the family experiences.

The ability of the family to protect the child from the effects of stressful events that take place in his/her life is sufficiently documented in the literature. Studies have shown that a supportive, warm, and secure family environment has a definite contribution to the adjustment of the child, and can act protectively against the development of psychological difficulties (Collishaw et al., 2007; Jaffee, 2007). Similar to this, studies have found that parental warmth is an essential ingredient of proper upbringing, and plays an important part in the social and emotional well-being of the child (Egeland, Kalkoste, Gottesman, & Erickson, 1990; Kim-Cohen, Moffit, Caspi, & Taylor, 2004). According to Patterson, Cohn and Kao (1989), children that are rejected by their schoolmates, and have a tender relationship with their mother, seem to face less behavioral problems. The overall atmosphere of an organized and supportive family environment appears to reduce the anxiety levels experienced by victims and increases the probability of their adjustment (Estevez, Musitu, & Herrero, 2005).

The type of parental behavior found to be most closely associated to the development of bullying behavior is the authoritarian parenting style (Baldry, & Farrington, 2000; Espelage et al., 2000; Knafo, 2003; Soenens, Duriez, & Hutsebaut, 2005). Authoritarian parents place many demands and expectations on their children, leave no room for negotiation, and do not respond to their needs (Knafo, 2003). The existence of this parental type increases the probability that the child will develop bullying behavior at school (Kaufmann et al., 2000).

Furthermore, the aggressive, rejective, and violent parental behavior (Pontzer, 2010), as well as the lack of emotional attachment to the child is positively correlated to the phenomenon of bullying (Jewell, Krohn, Scott, Carlton, & Mainz, 2008). Children exposed to such types of behavior may employ them in their own relationships with other people, the result being a lack of empathy for others and development of aggressive behavior, which is possibly going to include bullying (Lila, Garcia, & Garcia, 2007). From the data presented above, it becomes clear that when parents are not acting as positive role models for their children, and do not teach them how to behave, bullying behaviors are very likely to occur.

THE ROLE OF FATHER IN THE MENTAL HEALTH OF THE CHILD

It is only in the last two decades that the role of the father has been the object of systematic research and study. Research data concerning the paternal role in the life of the child were very sparse before the 1980s. Researchers used to characterize the father as the invisible parent, or the parent who cannot be easily approached (Herbert, & Carpenter, 1994). His role in the upbringing of the child was considered ancillary to that of the mother, and as a result his contribution to the child's development remained always in the background (Ang, 2006; Finley & Schwartz, 2006). Attachment theory seemed to support this view as, according to which, the father was not viewed as a primary attachment person like the mother, but rather as a less 'important' person, whose participation was restricted solely to providing material supplies and play (Bowlby, 1982).

THE DISTINCT ROLE OF THE PARENTS

According to subsequent research, the mother and father seem to have distinct roles regarding the development of the child, which operate complementary to one another (Craig, 2006; Parke, 2004). The first research questions regarding this approach were posed during the 1950s, by Parsons and Bales (1995, as is reported in the article by Finley, Mira, & Schwartz, 2008), who claimed that the role of the father mainly concerns areas such as financial provisions and discipline (instrumental functions), while the role of the mother concerns areas such as upbringing, companionship and participation in the free time (expressive functions). Contemporary research shows that this difference seems to be in effect even to our days, since it reflects the attitudes of young adults regarding the distinction of the parents and their contribution to children's development (Finley, et al., 2008; Finley, & Schwartz, 2006). On the other hand, there is the opposite perspective, which does not adopt this categorization and claims that the father, after the social changes that took place in the 1960's and 1970's, has already started to be actively involved in the upbringing of the child, to participate in activities inside the house, and to express himself in a more emotional way (Giele, & Holst, 2004; Marsiglio, Amato, Day, & Lamb, 2000).

Following the approach of Parsons and Bales, Gottman and his colleagues (1998) claimed that the experiences that a child has with his/her father affect specific areas of his/her development more, when compared with the experiences with his/her mother. For example, it has been found that paternal support to the efforts of the child for autonomy during the preschool years affects the emotional security experienced by the child during adolescence more than the maternal support (Gottman et al., 1998). Similar results were obtained with Asian participants, according to which, paternal influence seemed to affect to a greater extent the psychological adjustment of adolescents and the functionality of the family than maternal influence (Ang, 2006; Shek, 2001).

At different times, several models have been developed that refer to the areas of paternal involvement. According to the model proposed by Lamb, Pleck, Chernov, and Levine (1987), there are three dimensions of paternal involvement: a) *engagement*, which refers to the direct contact of the father with his child and the sharing of activities during their interaction, b) *availability*, which refers to the presence of the father, and how available he is to his child, and

c) *responsibility*, which refers to the duties the father has towards the child, such as organizing and planning his/her life, as well as the fulfillment of his/her needs (both material and emotional).

In a similar vein, based on the model of Lamb et al., (1987), Palkovitz (2002) describes three areas of paternal involvement (cognitive, emotional and behavioral) which overlap and are defined by factors such as the time the father spends with his child, the degree to which he is involved in his/her life, and how direct their interactions are. According to this model, a father can be involved in children's development in at least 15 different ways: through communicating, teaching, monitoring, engaging in thought processes, providing to the child's needs, showing affection, protecting, emotionally supporting, caregiving, engaging in child-related maintenance, being available, sharing interests with the child, sharing activities, planning, and through the father's running errands and doing favors for the child. Both models include behaviors which are frequently displayed by a man when he is a father.

What is of particular interest is that the extent of paternal involvement to the life of the child can be affected by several factors. The structure of the family, the relationships among its members, the gender, age and personality of the child, the father's views concerning the upbringing of the child, and the characteristics of the personality of the father and mother are only some of the factors that may affect the degree to which a father is involved in the life of his child (Cabrera, Fitzgerald, Bradley, & Roggman, 2007).

PATERNAL CONTRIBUTION TO THE DEVELOPMENT OF THE CHILD

Numerous research data confirm that the support and the involvement of the father to the life of the child has a positive effect to his/her development (Ang, 2006). Research data from the National Center for Educational Statistics-NCES (1997, as reported in the article by Flouri, Buchanan, & Bream, 2002) have demonstrated that children whose father plays an active role to their everyday life had the best academic performance, behavior, attitudes, and interpersonal relationships at school. The presence of the father also appears to positively affect cognitive and mental development of the child. More contemporary research has shown that children of supportive fathers have the tendency to exhibit better pro-social behavior and psychological adjustment, have better performance at school, less involvement in anti-social behaviors and, finally, have better interpersonal relationships (Rohner & Veneziano, 2001; Shek, 2001). Grossman and his colleagues in a research conducted in 2002, found that adolescents who felt security in their relationship with their father were more sensitive, receptive, and they responded to provocations of their schoolmates more effectively. The lack of paternal love seems to reinforce the manifestation of behavioral and psychological problems, while reducing the sense of well-being and security (Amato, 1994; Rohner & Veneziano, 2001; Veneziano, 2003). Absence of the father also seems to be associated with personality problems as well as difficulties with psychological adjustment (Amato, 1994), mental problems (Barrera Garrison-Jones, 1992), substance abuse problems and criminality (Repetti, Taylor, & Seeman, 2002).

Apart from research which examines in general the paternal involvement in the life of children, most contemporary research has focused on the extent to which paternal involvement can be used as an independent predicting factor for the development of psychological problems and negative behaviors in children. More specifically, it is examined whether paternal

involvement can explain part of the variance of factors concerning the mental health of the child, independently of the presence of maternal support (Veneziano, 2003). Initial results have demonstrated that, indeed, paternal love contributes as an independent predictive factor, while in some cases, it seems that it is the single factor predicting the elimination of a number of problems and negative behaviors in children (Rohner, 2004; Rohner, & Veneziano, 2001).

According to a research by Flouri et al. (2002), maternal and paternal support are independently associated with a positive attitude of adolescents towards school. In a similar research, it was found that involvement of the father was able to predict, independently from maternal involvement, the continuation of the academic studies of the adolescents at the age of twenty years (Flouri, & Buchanan, 2003). Related results were reported in a study by Veneziano in 2000, according to which only paternal warmth was statistically correlated with psychological adjustment of children.

Numerous research data indicate that the role of the father comprises an independent predictive factor in the appearance of specific types of psychopathology, such as substance abuse, depression, incidence of depressive emotion, as well as externalizing and behavioral problems (Rohner & Britner, 2002). Furthermore, Chen, Liu and Li (2000) found that only paternal warmth correlated negatively with the incidence of reactive aggression among peers, while it correlated positively with academic performance and social efficacy. Similarly, paternal love seems to contribute independently from maternal love to happiness of children, their satisfaction from life, decreased levels of psychological stress, as well as in overall mental well-being (Amato, 1994; Barnett, Marshall, & Pleck, 1992).

FATHER INVOLVEMENT AND BULLYING

Concerning incidents of bullying and the role of the father, despite the lack of sufficient research on this topic, the available research data indicate the following:

As far as boy-victims are concerned, fathers are usually either emotionally absent, or overly critical towards them (Olweus, 1993; Fosse & Holen, 2002). It is argued that sons, learn mainly from their fathers how to develop self-protective behaviors and ways of interacting with other children. Absence or problematic relations with the father, in those cases, in relation with over-protectiveness on the mother's part, renders the boy, usually, socially passive and less equipped to face the challenges of interpersonal relationships, especially the aggressive behaviors of their peers (Fosse & Holen, 2002). Unfortunately, to our knowledge there are no research data concerning the specific role of the father in the victimization of girls.

As far as bullies are concerned, existing data indicate that fathers are either absent, both emotionally and physically, or they exert their power through force and harsh physical punishment and violence, or, in other cases, are over-permissive and reinforce directly or indirectly the aggressive behaviors of their boys (Duncan, 1999).

Similarly, in the families of victims, the few available data indicate that fathers express a wide range of negative behaviors towards their children. These behaviors include, at one extreme, physical violence and negative emotions, and on the other extreme, indifference and emotional detachment (King, 2006). On the other hand, involved fathers seem to function protectively towards children-victims.

Other research data confirm this finding. In a research conducted by Frouri and Buchanan in 2002, including 1344 students from schools of Great Britain, the mediating role of paternal involvement to the degree of victimization and bullying incidents was examined. It was found that the existence of a supportive father can limit the negative impact of bullying and protect the victims from its more intense manifestations. According to the results of this research, paternal support was affecting the victims of bullying more often than the rest of the students, since it was functioning as a form of social support, protecting them from their negative experiences (Flouri & Buchanan, 2002).

In a similar research, it was found that victimization in school comprises a source of intense stress and affects the well-being of the child, as well as the sense of satisfaction it has regarding his/her own life (i.e., low self-esteem, negative self-image) (Olweus, 1993). Other researchers have confirmed that the existence of social support greatly contributes to the well-being and the prosperity of the student, even if the student has already experienced victimization (Rigby, 2002).

On the other hand, there are behaviors on behalf of the father that intensifies the importance of power and assertion over others, while at the same time place no limits to the child's aggressiveness, or directly reinforce it. Ladd has noted (1992) that children who have fathers with authoritarian or demanding behavior and who project patterns of power to their sons, are usually also emotionally detached; as a consequence, the child develops similar patterns of behavior towards his/her weaker peers, and most importantly, does not display any empathy to the sensitive or emotionally vulnerable individuals. In these cases, it is very important to stress the importance of clinical and counseling interventions that can - in combination with research data - offer us sufficient and useful information regarding the course of each child towards victimization and the importance of the father's role to his child's involvement to such incidents.

IMPLICATIONS FOR PRACTICE

Based on the data presented in this literature review, we should note that in counseling interventions emphasis should be given to certain parameters, such as the role of the parents, and especially that of the father. Clinical practice, as well as research, usually highlights for both groups - victims and bullies - a problematic relationship with the father (absence of paternal involvement, inefficient emotional investment/support, problematic family dynamics, etc.). Emotional motivation and involvement of the father in the emotional development of the children, consists in a lot of cases a vital parameter of counseling work.

For example, it has been systematically noted that paternal involvement is of paramount importance to children with anxiety disorders, children with low self-esteem, children that are introverted and socially inhibited and maintain dependent relationships to over-protecting mothers, but also to children with aggressive tendencies, that are involved in one way or another to similar phenomena (i.e. bullying/victimisation) (Caldwell, 1999; Keat, 1999). The reinforcement of the relationship with the father through counseling work, the restoration of mutual trust between parents and children, and the reinforcement of the child's self-esteem makes much easier the recognition as well as the reporting of bullying incidents on behalf of the child (Mackey & Immerman, 2004). In any case, as noted earlier, research has already

proven that the father, with his attitude, seems to play an important role both in the manifestation of and in the protection from bullying incidents, and consequently, his involvement is deemed absolutely necessary (Flouri & Buchanan, 2002).

In the last years, there has been an increase in intervention programmes which, gradually, have started to include in their approaches the active role of the father. This tendency appears to be the result of factors such as the gradual change of society's beliefs concerning parental roles, contemporary research data concerning the influence of the father to the development of the child (Thompson, 2003), as well as men's desire to actively seek information concerning fatherhood and their preparation for becoming fathers (Gage & Kirk, 2002).

The characteristics of the intervention programs vary depending on: the target they want to achieve, the kind of father to whom they are addressed, their content, as well as on the methods they are using (Gearing, Colvin, Popova, & Regehr, 2008). Some of them, aim at cultivating in the father the responsibility inherent in his role, as well as the emotional and financial commitment to his children. Other programs focus on the training of the parents and the whole family in general (e.g., Parent and Family Education PFE). Those programmes inform parents on the developmental stages of the child, their parental responsibilities, the different types of care available to them, as well as on matters related to their relationship to their children (Palm, 1997, as cited in the article of Gearing et al., 2008). Similarly, there are programs geared towards fathers who face special financial and socio-cultural challenges, such as adolescent fathers, divorced fathers, or fathers of different cultural backgrounds. Finally, some of them have a therapeutic orientation, and attempt to strengthen the self-confidence of the fathers so that they can face effectively the challenges of fatherhood (Gearing, et al., 2008). However, despite the existence of a satisfactory number of interventional programmes, participation in such programmes is strongly affected by different socioeconomic factors. As Raikes and Bellotti (2007) mention in their article, the existence of additional problems, such as underpaid jobs, unsteady employment, demands of the workplace, existence of mental disorders, problems with the law and unsteady residence, can impede the attempts of the father to get close to his child and contribute essentially to his/her development.

Another factor which prevents the father from being involved in his child's psychosocial development is the attitude of the mother herself regarding this effort. According to contemporary research, while fathers seem to be more motivated than in the past regarding the participation to interventional programmes (Raikes, Summers, & Roggman, 2005; Turbiville, Umbarger, & Guthrie, 2000), the perception of the mother that she is the sole responsible (and capable) parent for the upbringing of the child hampers their efforts. The research by Walker and McGraw in 2000 comes to the same conclusion, confirming the definite contribution of the mother both in the reinforcement of the father-child relationship, and in the decision of the father to participate in an interventional program. Specifically, the authors state that it is a very common phenomenon for the mother to organize her schedule in such a way as to be able to satisfy the needs of the child by herself, without giving to the father the chance to contribute to the needs of the child. For example, the mother, despite all the responsibilities she may have, tries to always pick up the child from school, without allowing the father to participate to the daily schedule of the child. In this way, the father is getting estranged and feels that his presence is redundant, resulting in his total resignation from the paternal role.

CONCLUSION

In concluding, what has become very clear is that the role of the father in the life of the child is no longer considered to be inferior to that of the mother. The wide range of research that revolves around the father, the factors which affect his behavior, the areas he is involved in, and the impact his behavior and his involvement have in the development of the child, prove how important his presence, his behavior, and his role is considered to be. Despite the different areas of involvement and the different roles the father has compared to the mother, what almost all research comes down to is that his presence, his positive relationship with the child, and his positive behavior contributes to the positive development of the child. The father should not be considered, and is not considered anymore, as less important to the child's development compared to the mother. He exerts the same influence as she does, albeit in a different way and in different areas some of the time. This is especially true in the case of bullying, since it has been shown that, especially for boys, the paternal involvement can be even more influential, compared to mother, regarding the prevention or the reinforcement of the phenomenon.

The active involvement of the father in such activities is necessary, since his role in the general mental well-being of the child is considered to be important. Holistic interventions for the combat of bullying, which take place at the earliest possible stage, and which presuppose the participation and the conscious effort of both parents comprise, most likely, the most effective solution towards this direction.

ABSTRACT

Bullying victimization is a major public health problem among adolescents. It is associated with poor academic performance, anxiety, depression and suicidal behaviors. There are limited reports on victimization from bullying among Botswana adolescents. The purpose of this study was to determine the correlates for bullying victimization among school-going adolescents in Botswana. The 2005 Botswana Global School-based Health Survey (GSHS) data were obtained from the World Health Organization. A weighted analysis was conducted using statistical software (SPSS version 15.0). We estimated the prevalence of bullying victimization and conducted logistic regression analysis to estimate associations between the outcome (bullying victimization) and selected explanatory variables. Out of 2,165 in-school adolescents who participated in the study, 51.3% (54.2% males and 52.2% females; $p=0.086$) reported having been bullied in the last 30 days. In multivariate analysis, bullying victimization was positively associated with physical fighting (OR=2.17; 95% CI [1.73, 2.73]), truancy (OR=1.84; 95% CI [1.35, 2.50]), and alcohol drinking (OR=1.41; 95% CI [1.04, 1.91]). Victimization is prevalent among in-school

adolescents in Botswana. Efforts to prevent and control bullying should take into consideration the factors identified in this study.

INTRODUCTION

Where data are available, bullying victimization is prevalent globally with significant regional variations in the rates of victimization (1-2). In a study on bully victimization among in-school adolescents from five continents, Due et al (2) reported the highest prevalence for bullying victimization among boys was in Zimbabwe (70.2%), while Zambia had the highest prevalence for girls (67%). Adverse conditions positively associated with victimization from bullying include serious injuries (3), alcohol and drug use (4), truancy (5), depression (6) and suicidal behaviors (7).

Bullying victimization is common in Botswana among school going adolescents. Fleming and Jacobsen (4) reports rates of being bullied as high as 53.0% with no sex difference (52.2% of females and 54.2% of males). They also considered factors (age, sex, symptoms of depression) associated with being bullied in their study but in their analysis they used the relative risk as a measure of the magnitude of association. Unfortunately the relative risk is not an appropriate measure of association in cross sectional studies. The purpose of this study was to re-analyze the data on correlates for bullying victimization among school-going adolescents in Botswana so that we may provide public health officers with correct results for use in interventions.

OUR STUDY

This study was based on a secondary analysis of data from the Botswana Global School-based Student Health Survey (GSHS) that was conducted in 2005. The 2005 Botswana GSHS was a school-based survey which included students in classes with the majority ages of 13-15 years. A two-stage cluster sampling design was used to produce data that was representative of students in the country. At the first stage, schools were selected with probability proportional to enrolment size. At the second stage, classes were randomly selected and all students in selected classes were eligible to participate. There was no replacement of students who were not available despite being in the selected schools. Students self-completed the questionnaires and the responses to questions were indicated on a computer scannable answer sheet.

In order to assess history of victimization from bullying, the question that was asked was: During the past 30 days, on how many days were you bullied? Possible responses included 0 days or any number of days. In terms of involvement in a physical fight, students were asked the question: During the past 12 months, how many times were you in a physical fight? Options included 0 times, one up to 12 or more times.

These data were obtained from the World Health Organization. The study was approved by the Botswana Ministry of Health. Parents were informed of the study through a letter, and students gave verbal consent to participate in the survey. To preserve individual confidentiality, the questionnaire was anonymously self-reported by the students.

Cases with missing values were not considered in the analysis. A weighting factor was used in the analysis to account for differences in the probability of selecting a school and classroom, and to account for differences in non response rates for various strata.

Data were first analyzed using SPSS version 11.5. Unweighted frequencies and their weighted percentages are reported. For the main outcome (bullying victimization), we recoded the responses in two categories: 0 for not having been victimized in the past 30 days, and 1 for having been victimized in the past 30 days. We conducted bivariate and multivariate logistic regression analyses in order to estimate associations between independent factors and the outcome variable. The hypotheses were "There were no significant associations between socio-demographic factors and bullying victimization". We report prevalence of bullying victimization as well as the unadjusted odds ratios (OR) and adjusted odds ratios (AOR) together with their 95% confidence intervals (CI).

Table 1. Socio-demographic characteristics and bullying victimization of the study population

FINDINGS

A total of 2,165 students participated in the 2005 Botswana GSHS; and 1829 had information on whether they were bullied or not. Overall, 42.4% were depressed; 22.5% consumed alcohol; and 8.7% had used illicit drugs. More than 1 in five (22.5%) participants reported having missed classes without permission. Altogether, 53.1% (54.2% of male and 52.2% of female) participants reported having been bullied in the previous 30 days to the survey. Further description of the sample by gender is shown in Table 1.

Table 2 reports associations between being bullied and selected factors. Being bullied was positively associated with having engaged in physical fighting (OR=2.17; 95% CI [1.73, 2.73]), self reported feelings of depression (OR=1.40; 95% CI [1.16, 1.77]); truancy (OR=1.84; 95% CI [1.35, 2.50]); and alcohol drinking (OR=1.41; 95% CI [1.04, 1.91]).

DISCUSSION

In a study of bullying victimization among in-school adolescents in Botswana, we found that 53.1% of the respondents were bullied in the last month. This prevalence is higher than the average (32%) for 66 countries and territories from five continents (2). In Africa, that prevalence is lower than 62.8% reported in Zambia (9), but higher than 40.1% in Ghana (8) and 39.6% in neighboring Swaziland (5).

We found that bullying victimization was positively associated with reported depression, having engaged in physical fighting, truancy, and alcohol drinking. In a study of the association between bullying and psychological health among senior high school students in Ghana, Owuso et al found that bullying victimization was positively associated with depression, suicide ideation, and loneliness (8). The association between bullying victimization and physical fighting was reported previously in other settings such as Zambia (9), Philippines (10) and China (11). In a study of the association between physical bullying victimization and physical fighting among Filipino school going adolescents, Rudatsikira et al reported a dose-response relationship between the two (10). Previous studies have reported the relationship between bullying victimization and alcohol use and other substances (12,13).

In this study, there was no significant gender difference in bullying victimization. Some studies have reported similar findings (8,10) while others have reported that males were more likely to be bullied than females (9,11). What is consistent in the literature is the gender difference in the types of bullying victimization; males are more at risk for physical victimization while females are more at risk of relational or emotional victimization (14-15).

The present study has several limitations and strengths. Data were collected through self-reports. To the extent that study participants mis-reported, intentionally or not, our findings may be biased. The study design was cross sectional which limits us from ascribing causation between the outcome and explanatory variables. It is also important to note that different studies have defined bullying differently. For instance, Sourander et al (16) defined bullying as "an aggressive act embodying an imbalance of power in which the victims cannot defend themselves accompanied by an element of repetition." Our study only asked whether students had been bullied. However, the sample size was large thus improving precision of the effect measure estimates. That this study is a secondary analysis of existing data can be both a strength and a weakness. A strength in that the subjects' responses could be accurate as study

participants may not have anticipated any links between outcome variable and explanatory variables, hence truthful reporting; and a weakness in that there are likely to be several unmeasured confounders that a primary study could have planned to measure.

Table 2. Factors associated with being bullied

Factor	Bullied n (%)	OR ¹ (95% CI ³)	AOR ² (95% CI)
Age (years)			
< 14	89 (9.2)	0.95 (0.67-1.35)	1.12 (0.76-1.67)

Yes	238 (30.7)	2.44 (1.90-3.13)	1.41 (1.04-1.91)

¹OR Unadjusted odds ratio.

²AOR Adjusted odds ratio.

³CI confidence interval.

CONCLUSION

In this study, we found that bullying victimization was prevalent among school-going adolescents in Botswana. Efforts to prevent and control bullying should take into consideration the factors identified in this study.

ACKNOWLEDGMENTS

We thank the World Health Organization for availing the data for further analysis and the students for their participation in the survey.

ABSTRACT

Adolescent violence is a very visible phenomenon in our modern society, where you just have to open the newspaper or the television and you find yourself right in the middle of it. In order to understand the scope of the problem, we need to look at the epidemiology of global violence. Each year, more than 1.6 million people worldwide lose their lives to violence and for every person who dies as a result of violence, many more are injured and suffer from a range of physical, sexual, reproductive and mental health problems. Violence places a massive burden on national economies in health care, law enforcement and lost productivity. We are talking about a major public health problem. Programs for intervention have been researched and long-term follow-up indicates that early intervention is working and even if such programs would seem to demand a substantial economic investment, they have been proven cost-effective in the long run.

INTRODUCTION

Adolescent or youth violence is a very visible violence in our modern society, where you just have to open the newspaper or the television and you find yourself right in the middle of it. In order to understand the scope of the problem, we need to look at the epidemiology of global violence. In 1996 the World Health Assembly declared violence a leading public health issue (1) and as a result of this resolution a comprehensive report was published in 2002 (2).

The World Health Organization (WHO) defined violence as: "The intentional use of physical force or power, threatened or actual, against oneself, another person, or against a group or community, that either results in or has a high likelihood of resulting in injury, death, psychological harm, maldevelopment or deprivation" (3).

The World Health Organization's Global Burden of Disease project for 2000 (2) estimated that 1.6 million people (28.8 per 100,000) worldwide died as a result of self-inflicted, interpersonal or collective violence. In this 2000 project an estimated 199,000 adolescent homicides (9.2 per 100,000) occurred globally or about 565 adolescents died each day due to interpersonal violence with variations around the globe. Homicide rates were 0.9 per 100,000 in countries like Europe, 17.6 per 100,000 in Africa and 36.4 per 100,000 in Latin America (2). So we indeed live in a violent world, but there has been a downward trend between 1990 to 2000 from a violence related death rate of 35.3 to 28.8 per 100,000 (2,4). Each year, more than 1.6 million people worldwide lose their lives to violence (5). For every person who dies as a result of violence, many more are injured and suffer from a range of physical, sexual, reproductive and mental health problems. Violence places a massive burden on national economies, costing countries billions of US dollars each year in health care, law enforcement and lost productivity (5).

TRENDS IN ADOLESCENT HOMICIDE

In the years between 1985 and 1994 the adolescent homicide rates increased in many parts of the world. There was a sharp increase for males (it doubled), while the trend for females was steady. The increase was seen in developing countries and economies in transition with the most common method of attack by firearm. Dramatic increase was seen in the age group of 10-24 year olds in the Russian Federation after the collapse of communism with a 150% increase from 7.0% to 18.0 per 100,000. Decrease was seen in Canada and Australia, while both the United States and New Zealand had increase (2).

Between 1970 the early 1990s, the homicide rate for teens ages 15 to 19 more than doubled, from 8.1 to a peak of 20.7 per 100,000 in 1993 (7). The rate declined steeply during the late 1990s, then leveled out at around nine deaths per 100,000 between 2000 and 2004. Although the rate of homicides increased between 2004 and 2006, to 10.7 deaths per 100,000, it has since decreased. In 2010, the homicide rate was 8.3 deaths per 100,000, the lowest it has been since before 1980 (7).

Risk factors can be divided into four categories (8): Family factors such as a firearm at home, low income, domestic violence, teen parents or divorce; Social factors such as ethnic heterogeneity, crowded housing, racial intolerance, lack of adult supervision and social acceptance of violence; Psychological factors such as depression, antisocial behavior, conduct

disorder or aggression; and Personal factors such as male gender, alcohol or drug abuse, poor impulse control, previous gunshot injury and minority race.

TRENDS IN ADOLESCENT SUICIDE

Suicide is the third leading cause of death among adolescents with a fivefold increase seen for example in the United States for the period 1950-1990 (8). In 2010, rates of suicide among male teens were highest among American Indians (24.3 per 100,000) and whites (14.2), followed by Hispanics at 8.1, blacks at 6.8, and Asian or Pacific Islanders at 6.3 per 100,000 (7). Among females, American Indian teens had the highest rate at 11.0 per 100,000, followed by white teens at 3.5, Hispanic teens at 2.9, and Asian or Pacific Islanders with 3.1, with black teens at 1.1 per 100,000 (7).

Firearms and alcohol are also here important risk factors (4-7) and gender. Adolescent females attempt more suicided, but males have a higher completion rate due to the use of more lethal means (like a firearm).

TRENDS IN NON-FATAL VIOLENCE

For every adolescent homicide there is about 20-40 victims of non-fatal youth violence (2). Here still males are most often involved, but fewer firearm involvement and instead fists and feet and other weapons like knife and clubs (2).

TRENDS IN SCHOOL VIOLENCE

Research into school violence took off in Scandinavia and the United kingdom in the 1980s and together with the WHO cross national studies (37 countries) on health behavior in school aged children (HBSC) is conducted every fourth year (9). Bullying in schools varied from 15.7% in Sweden to 68.5% in Lithuania and with 50.0% in Israel (9).

According to the CDC's School Associated Violent Death Study, between 1% and 2% of all homicides among school-age children happen on school grounds or on the way to and from school or during a school sponsored event (10). In a 2011 nationally representative sample of youth in grades 9-12 (11):

- 12% reported being in a physical fight on school property in the 12 months preceding the survey
- 16% of male students and 7.8% of female students reported being in a physical fight on school property in the 12 months preceding the survey
- 5.9% did not go to school on one or more days in the 30 days preceding the survey because they felt unsafe at school or on their way to or from school
- 5.4% reported carrying a weapon (gun, knife or club) on school property on one or more days in the 30 days preceding the survey

- 7.4% reported being threatened or injured with a weapon on school property one or more times in the 12 months preceding the survey

EXAMPLES FROM OUR DAILY PRACTICE

We would like to share a few stories from our experience with adolescents on a daily basis:

- Two thirteen-year-old boys were arrested for breaking into air-conditioning units in the neighborhood to steal Freon. Obviously they use it for huffing, to get high. Upon interviewing them after being consulted by the social services, one of the boys said: “I am bored, my parents are working and I have nothing to do after school so we wanted to get high and forget about life’s problems”
- A young man of 14 years of age was admitted after attempting suicide. He said his life was basically good, but he became worried that maybe he is not a real man, since he noticed that his breasts are growing and he is looking more like a girl
- Several young teens between the ages of 13-15 years were diagnosed with gonorrhea tonsillitis. They said they were not sexually active, but have participated in “head parties” with other peers. It was revealed that these parties referred to gathering of young teens to have oral sex.
- A 16-year-old girl was referred for evaluation of depression and weight loss. She disclosed that she had been sexually assaulted by her stepfather for the last two months. When we tried to line up her mother’s help we got exactly the opposite: the mother threatened to kick the “liar” out of the home without even listening to the whole story.

We also see our fair share of good stories with teens doing good deeds and achieving high levels of success. It is the bad stories, however, that grab our attention, because of their sad and tragic consequences and our desire to understand why they happen. In countries like the United States of America the leading causes of mortality continue to be accidents, homicide, suicide, sexually transmitted infections and teen pregnancy. All are preventable yet they continue to happen. So whom should we blame? The parents for being busy and/or uneducated, the media for portraying sex, drugs and violence as a “normal” way of life, the school system for not educating our kids about real life, the health care industry that continues to deprive many of our teens access to health care, or our local and federal leaders both political and religious for giving bad examples with their continuing scandals of corruption and inappropriate sexual conduct!

It would be extremely simplistic to say that one or the other bears the blame. With the technological advances and the availability of modern communication systems including the internet, our teens are bombarded with a sea of information that is frequently inaccurate or age-inappropriate. The literature and real life experience are overall in agreement that improvement of all aspects of our societies is needed to help prevent many of our teens’ problems. The parents should do their part in finding a way to spend quality time with their kids and to educate them on all aspects of life. Schools should do a better job of teaching real life skills and knowledge rather than purely academic subjects only. As a society, we should be able to provide better environment and health care for our adolescents. Our leaders should be providing good

examples and so should the celebrities. If each one of us contributes, maybe we can improve our future by improving the current status of our adolescents who are our future.

HOME VISITATION

One type of prevention programs that has proven effective is home visitation. Such programs date back nearly 100 years in Scandinavia, the United Kingdom and even in the United States with research showing the positive long-term effects (12). Prenatal and early childhood nurse home visitation (two years after birth) can reduce serious antisocial and criminal behavior shown by a 15 year closely follow-up study (12).

CONCLUSIONS

In recent years a growing body of research on adolescent violence has shown the epidemiology on a global basis and confirmed that we are talking about a major public health problem. Programs for intervention have also been researched and long-term follow-up (12) indicates that early intervention is working. Such programs would seem to demand a substantial economic investment, but proven cost-effective in the long run (13).

Bullying victimization is a major public health problem among adolescents. It is associated with poor academic performance, anxiety, depression and suicidal behaviors. There are limited reports on victimization from bullying among Botswana adolescents. The purpose of this study was to determine the correlates for bullying victimization among school-going adolescents in Botswana. The 2005 Botswana Global School-based Health Survey (GSHS) data were obtained from the World Health Organization. A weighted analysis was conducted using statistical software (SPSS version 15.0). We estimated the prevalence of bullying victimization and conducted logistic regression analysis to estimate associations between the outcome (bullying victimization) and selected explanatory variables. Out of 2,165 in-school adolescents who participated in the study, 51.3% (54.2% males and 52.2% females; $p=0.086$) reported having been bullied in the last 30 days. In multivariate analysis, bullying victimization was positively associated with physical fighting (OR=2.17; 95% CI [1.73, 2.73]), truancy (OR=1.84; 95% CI [1.35, 2.50]), and alcohol drinking (OR=1.41; 95% CI [1.04, 1.91]). Victimization is prevalent among in-

* Corresponding Author's Email: ssiziya@gmail.com.

school adolescents in Botswana. Efforts to prevent and control bullying should take into consideration the factors identified in this study.

INTRODUCTION

Where data are available, bullying victimization is prevalent globally with significant regional variations in the rates of victimization (1-2). In a study on bully victimization among in-school adolescents from five continents, Due et al (2) reported the highest prevalence for bullying victimization among boys was in Zimbabwe (70.2%), while Zambia had the highest prevalence for girls (67%). Adverse conditions positively associated with victimization from bullying include serious injuries (3), alcohol and drug use (4), truancy (5), depression (6) and suicidal behaviors (7).

Bullying victimization is common in Botswana among school going adolescents. Fleming and Jacobsen (4) reports rates of being bullied as high as 53.0% with no sex difference (52.2% of females and 54.2% of males). They also considered factors (age, sex, symptoms of depression) associated with being bullied in their study but in their analysis they used the relative risk as a measure of the magnitude of association. Unfortunately the relative risk is not an appropriate measure of association in cross sectional studies. The purpose of this study was to re-analyze the data on correlates for bullying victimization among school-going adolescents in Botswana so that we may provide public health officers with correct results for use in interventions.

OUR STUDY

This study was based on a secondary analysis of data from the Botswana Global School-based Student Health Survey (GSHS) that was conducted in 2005. The 2005 Botswana GSHS was a school-based survey which included students in classes with the majority ages of 13-15 years. A two-stage cluster sampling design was used to produce data that was representative of students in the country. At the first stage, schools were selected with probability proportional to enrolment size. At the second stage, classes were randomly selected and all students in selected classes were eligible to participate. There was no replacement of students who were not available despite being in the selected schools. Students self-completed the questionnaires and the responses to questions were indicated on a computer scannable answer sheet.

In order to assess history of victimization from bullying, the question that was asked was: During the past 30 days, on how many days were you bullied? Possible responses included 0 days or any number of days. In terms of involvement in a physical fight, students were asked the question: During the past 12 months, how many times were you in a physical fight? Options included 0 times, one up to 12 or more times.

These data were obtained from the World Health Organization. The study was approved by the Botswana Ministry of Health. Parents were informed of the study through a letter, and students gave verbal consent to participate in the survey. To preserve individual confidentiality, the questionnaire was anonymously self-reported by the students.

Cases with missing values were not considered in the analysis. A weighting factor was used in the analysis to account for differences in the probability of selecting a school and classroom, and to account for differences in non response rates for various strata.

Data were first analyzed using SPSS version 11.5. Unweighted frequencies and their weighted percentages are reported. For the main outcome (bullying victimization), we recoded the responses in two categories: 0 for not having been victimized in the past 30 days, and 1 for having been victimized in the past 30 days. We conducted bivariate and multivariate logistic regression analyses in order to estimate associations between independent factors and the outcome variable. The hypotheses were "There were no significant associations between socio-demographic factors and bullying victimization". We report prevalence of bullying victimization as well as the unadjusted odds ratios (OR) and adjusted odds ratios (AOR) together with their 95% confidence intervals (CI).

FINDINGS

Table 1. Socio-demographic characteristics and bullying victimization of the study population.

Factor	Male n (%)	Female n (%)	Total (%)
Age (years)			
< 14	78 (8.0)	131 (11.0)	209 (9.7)
14	190 (19.5)	302 (25.3)	492 (22.7)
15	319 (32.8)	372 (31.2)	6 (1.9)
16 +	385 (39.6)	388 (32.5)	773 (35.7)
Physical fight			
No	458 (47.1)	691 (58.3)	1149 (53.3)
Yes	514 (52.9)	494 (41.7)	1008 (46.7)
Parental supervision			
No	326 (34.5)	348 (30)	674 (32)
Yes	618 (65.5)	811 (70)	1429 (68)
Depression			
No	569 (59.6)	651 (55.7)	1220 (57.5)
Yes	385 (40.4)	518 (44.3)	903 (42.5)
Cigarette smoking			
No	817 (89)	1083 (95.2)	1900 (92.4)
Yes	101 (11)	55 (4.8)	156 (7.6)
Alcohol drinking			
No	596 (75.9)	795 (78.8)	1391 (77.5)
Yes	189 (24.1)	214 (21.2)	403 (22.5)
Drug use			
No	840 (86.3)	1138 (95.4)	1978 (91.3)
Yes	133 (13.7)	55 (4.6)	188 (8.7)
Truancy			
No	665 (70.2)	950 (80.3)	1615 (75.8)
Yes	282 (29.8)	233 (19.7)	515 (24.2)
Bullied			
No	377 (45.8)	481 (47.8)	858 (46.9)
Yes	446 (54.2)	525 (52.2)	971 (53.1)

A total of 2,165 students participated in the 2005 Botswana GSHS; and 1829 had information on whether they were bullied or not. Overall, 42.4% were depressed; 22.5% consumed alcohol; and 8.7% had used illicit drugs. More than 1 in five (22.5%) participants reported having missed classes without permission. Altogether, 53.1% (54.2% of male and 52.2% of female) participants reported having been bullied in the previous 30 days to the survey. Further description of the sample by gender is shown in Table 1.

Table 2 reports associations between being bullied and selected factors. Being bullied was positively associated with having engaged in physical fighting (OR=2.17; 95% CI [1.73, 2.73]), self reported feelings of depression (OR=1.40; 95% CI [1.16, 1.77]); truancy (OR=1.84; 95% CI [1.35, 2.50]); and alcohol drinking (OR=1.41; 95% CI [1.04, 1.91]).

Table 2. Factors associated with being bullied.

Factor	Bullied n (%)	OR ¹ (95% CI) ³	AOR ² (95% CI)

DISCUSSION

In a study of bullying victimization among in-school adolescents in Botswana, we found that 53.1% of the respondents were bullied in the last month. This prevalence is higher than the average (32%) for 66 countries and territories from five continents (2). In Africa, that prevalence is lower than 62.8% reported in Zambia (9), but higher than 40.1% in Ghana (8) and 39.6% in neighboring Swaziland (5).

We found that bullying victimization was positively associated with reported depression, having engaged in physical fighting, truancy, and alcohol drinking. In a study of the association between bullying and psychological health among senior high school students in Ghana, Owuso et al found that bullying victimization was positively associated with depression, suicide ideation, and loneliness (8). The association between bullying victimization and physical fighting was reported previously in other settings such as Zambia (9), Philippines (10) and China (11). In a study of the association between physical bullying victimization and physical fighting among Filipino school going adolescents, Rudatsikira et al reported a dose-response relationship between the two (10). Previous studies have reported the relationship between bullying victimization and alcohol use and other substances (12,13).

In this study, there was no significant gender difference in bullying victimization. Some studies have reported similar findings (8,10) while others have reported that males were more likely to be bullied than females (9,11). What is consistent in the literature is the gender difference in the types of bullying victimization; males are more at risk for physical victimization while females are more at risk of relational or emotional victimization (14-15).

The present study has several limitations and strengths. Data were collected through self-reports. To the extent that study participants mis-reported, intentionally or not, our findings may be biased. The study design was cross sectional which limits us from ascribing causation between the outcome and explanatory variables. It is also important to note that different studies have defined bullying differently. For instance, Sourander et al (16) defined bullying as "an aggressive act embodying an imbalance of power in which the victims cannot defend themselves accompanied by an element of repetition." Our study only asked whether students had been bullied. However, the sample size was large thus improving precision of the effect measure estimates. That this study is a secondary analysis of existing data can be both a strength and a weakness. A strength in that the subjects' responses could be accurate as study participants may not have anticipated any links between outcome variable and explanatory variables, hence truthful reporting; and a weakness in that there are likely to be several unmeasured confounders that a primary study could have planned to measure.

CONCLUSIONS

In this study, we found that bullying victimization was prevalent among school-going adolescents in Botswana. Efforts to prevent and control bullying should take into consideration the factors identified in this study.

ACKNOWLEDGMENTS

We thank the World Health Organization for availing the data for further analysis and the students for their participation in the survey.

Chapter 101

WORKPLACE AND BULLYING

Said Shahtahmasebi*, PhD

The Goodlife Research Centre Trust, Rangiora. New Zealand

ABSTRACT

A working environment is bullying and unsafe as long as your manager believes that being a 'team player' means loyalty to your manager and doing as you are told. Unfortunately, the literature on bullying concentrates on the characteristics of victims and the impact of bullying on their lives. The literature offers very little on how to prevent and eradicate bullying. Instead, the literature's solution is to offers ways of preparing potential victims. The problem with this approach is that while it does not address bullies and bullying it can also lead to confrontation and more bullying especially covert bullying. The literature on bullying in the workplace describes the mental and physical ill-health suffered by the victims and their families. The literature also discusses methods of bullying such as overt and covert, as well as physical and psychological abuse. The implications are that the consequences of abuse go far beyond the intended target; from the impact on the working environment to an individuals' health to economic and financial loss. The literature suggests various recommendations to employers and managers to combat bullying at work. However, the common assumption within the literature has been that the bullying is done by a colleague, a line manager or middle manager. Furthermore, it is often, wrongly, assumed that the executive/vice-chancellor, human resources, the trustees or the governing body are unaware of bullying in their workplace. Rate of workplace bullying is consistently highest in the Education and health sectors. This high rate of bullying can only be sustained if the management culture, wittingly or unwittingly, is one of bullying. In this chapter it is argued that cases of bullying whether due to isolated individuals, competition, rivalry, power or pure meanness as reported in the literature, can only thrive in a bullying management culture. Therefore, debate and policy formulation must be directed at government level in the first instance. The case reported is intended to raise some relevant issues to stimulate a debate and more research in this area.

INTRODUCTION

Much of the bullying literature is based on the premise of a bully with at least one victim, and offering suggestions on how parents, teachers, authorities, employers, and workforce can identify bullies in order to combat bullying. Very few authors discuss the possibility that bullies thrive when the workplace culture together with employment laws is conducive to supporting and encouraging bullying. For example, in some organisations, the executive management believes that loyalty means that staff must do what they are told i.e., loyalty to the executive rather than the organisation's goals, this will have a major impact on how senior and middle management behave and manage their staff. In this chapter the main issues of workplace bullying is raised and demonstrated through a case report.

Much has been written about the consequences of bullying as a social problem both in school and the workplace. The literature covers the various aspects of bullying e.g theoretical considerations (1), management environment and gender (2), psychological violence, misplaced loyalty and methods of bullying (e.g overt: visible physical and mental abuse, and covert: subtle abuse) (3), the effects of bullying (4-7), bullying at school (8), (9-11), and causes of bullying (12,13). McAvoy and Murtagh (14) provide a brief description of workplace bullying. An example of overt and covert abuse by an employer is demonstrated in a case narrative (15). Various authors make recommendations to the employers in order to combat bullying in their work environment (16). Glendinning (17) suggests that it is the role of human resources to deal with bullying and administer relevant policies in the workplace which often has tremendous implications for the organisation.

Most studies of bullying have concentrated on the victims' characteristics. Very few people ever victimise themselves; to have a victim there must be a seeker (18). Human interaction is a process and therefore is governed by dynamic codes of conduct. Some individuals, for whatever reasons, breach these codes to inflict suffering on others with whom they are bound by and share a common goal; through the organisational policy objectives and contracts. Very few studies have paid attention to studying the characteristics of the organisations, the bullies or the environments where bullies thrive. An important question to ask is what governs these individuals' behaviour? Without a proper study design to treat bullying as a process and to include the dynamics of human behaviour, our understanding of bullying behaviour could be vague and confused and at best one-sided. For example, Einarsen (12) in attempting to address the nature and causes of bullying on the one hand reports that the victims of harassment are more oversensitive, suspicious and angry, have low self-esteem and are anxious. On the other hand Einarsen argues that the personality of the victim may provoke aggression in others. Einarsen quotes competition, envy and the aggressor's own self doubt as three main reasons for bullying. However, these results were based on a subjective survey of the victims. The author, quite correctly, reports that without longitudinal studies personality factors may well be the outcome of bullying. It is not surprising then that assertiveness in the workplace is advised (19). Indeed, most employers, through their human resources (HR) division, offer staff self-development/assertiveness courses.

There are a number of problems with this strategy. There are no clearly defined boundaries for when assertiveness becomes aggression and bullying. What good will assertiveness or any anti-harassment policy do in a working environment and culture based on fear amongst staff, rumours, lies, falsifying of facts and misinformation and so on often referred to as predatory

bullying (12)? And what are the implications of implementing recommendations from poorly designed studies and lack of real evidence? For example, Manthei's (20) comparison of methods of teaching assertiveness is flawed and lacks academic rigour; it appears to breach ethics regulations, is a badly designed and poorly conducted study with an inappropriate methodology that does not relate to the aims of the study. The author's conclusions appear to be her own views and do not relate to the results. Therefore, policies developed based on such studies will create more problems for the organisations rather than resolving.

For practical purposes, perhaps, the brief discussion by McAvoy and Murtagh (14) provides a more comprehensive collection of issues from the prevalence of morbidity in the individual victims to the morbidity of the workplace environment. They also report that apart from the negative effects on physical and mental well being, bullying can have negative cognitive effects e.g lack of initiatives. Such practices will not be without economic and other social consequences. For example, McAvoy and Murtagh report that statistics from the UK national workplace bullying advice line suggest 20% of the cases are from the education sector, 12% from health care followed closely by 10% from social services. It is not therefore surprising that the associated costs of bullying in the UK alone is estimated at £2-30bn per annum. Similarly, a Canadian report (21) suggests a cost to employers of \$3.5bn and when the costs of wage replacement, health and medical care are included the costs are estimated at \$16bn. See also Sheehan for the Australian experience (22).

Bullying and harassment, though studied as one phenomena, take different forms and shape. However, it is argued that bullying thrives in an environment where the organisation has a bullying culture (4,12). Examples of harassment may include belittling opinion, public humiliation, withholding of access to training, unnecessary disruption, obstruction, threats of dismissal, shifting of goalposts, removal of responsibility, undue pressure to produce work (4). Sheehan (22) reports psychological abuse in the workplace and discusses the damage caused, and the legal and economic risks to organisations that fail to address the problems.

A STORY

Unsurprisingly, the case report concerns a tertiary education institution. The subject has kindly given permission to outline some of the main events representing unprofessional behaviour by the institution – in order to maintain anonymity details of events have been kept to a minimum.

The subject accepted an offer of a post from an educational establishment. The subject was brought in with the specific mandate to carry out research and development (R & D), consultancy with a small teaching component. The advertisement and the bump gave a positive picture of the institution using phrases such as a highly supportive, friendly and dynamic working environment, teaching staff expert in their fields, high quality research and researchers with international standing and so on. A quick internet search established that the claims about international standing was standard hype and by dynamic it was meant a high staff turn-over. The subject's final choice over other job offers was influenced by the challenges of the post.

One of the subject's mandates was to identify problem areas and report them to the management. Initially, things got onto a flying start and despite the negative rumours about the

institution and the management a number of initiatives got underway. These initiatives proved popular with staff. Within the first few weeks of starting work, the subject realised that the institution had huge problems in terms of culture, management style, staff and above all vision. All the management posts had been filled via internal promotions despite attracting credible and well-qualified external candidates and against the wishes of staff members who participated in the selection process. Most of the managers/staff had been in the same institution for many years. The existence of tribalism suggested the divide and rule style of management. Access to resources in particular to do research is the privilege of those belonging to the right tribe. Symbolism appears the central driving force in management style and staff perceptions of status. For example, office size and position and job title (e.g team leader) signifies academic status as opposed to experience, qualification and performance. The institution is being administered by staff without relevant management experience (in particular people skills) and qualifications. These internal appointments were apparently made after open competition with staff competing with credible, well-qualified and highly experienced candidates. Clearly, such a management style is a recipe for disaster particularly where new blood is recruited to carry out the education developmental work and delivery. The subject reported that the frustration of experienced and qualified staff working under such management had soon given way to friction and confrontation which quickly turned to hostility, abuse and harassment.

The subject made a report to the management based on the above observations and suggested that for the institution to achieve its goals a more supportive management practice was essential. In the report the subject further suggested that change in practice and recruitment of new blood at senior level to be a necessity. Moreover, the report recommended that as a first step the institution needed to consider a retraining programme for its current managers. With hindsight, the management did not want to see that kind of report! What followed next was months (nearly three years) of a sustained campaign against the subject. The initiatives one by one, without justification and in breach of the institution's own policies, were cancelled, the subject was excluded from input and contribution, workload was increased, rumours about the subject were spread. Consultations with the HR and their promise of resolving the situation was not only fruitless but also led to further campaigns. Included in the arguments with the management was the treatment of staff. However, the subject underestimated the fear amongst the staff; their unwillingness to demand their own rights and were prepared to be passive bystanders grateful for having a job, summarised the workplace culture of the institution. Managers with no track record and experience in R & D suddenly became experts and criticised the subject. Needless to say that the subject was quick and efficient in dismissing such criticism, which appeared to make the matters worse and help the campaign against the subject to intensify. Delaying tactics and obstruction also included intrusion, not processing of forms until after the closing date, access to personal files/materials without the knowledge or permission of the subject, interfering with processes, contacting external agencies with the specific view of obstructing the subjects progress. The subject reported these as the institution's immoral activities and malpractice by design.

The subject reported wondering if the management was so critical why would they not call a meeting with a view of terminating the contract. Not surprisingly, some material and statistics that became available through the unions revealed an unwritten policy of not to terminate contracts for fear of legal repercussion, that the senior management including HR had a history of aggressive behaviour and harassment against staff, were engaged in spreading rumours, setting up colleagues against colleagues, obstruction, positive support for the subject from other

heads of department being falsified as negative, threatening behaviour, instead of following complaint procedures the management met every complaint with a counter complaint, and, the use of their external social contacts to obstruct. It also revealed consistent complaints against the same managers and pattern of behaviour by the institution (similarly using humiliation, threats, undermining, belittling etc): the victims were either silenced, had to leave their posts or on long-term sick leave whilst the offending managers received promotion! In fact, during a face-to-face conversation about the structure of the institution and procedures with the head of department, the subject was told that the head was the real decision maker pointing out that there was no point contacting even the executive/vice-chancellor.

The subject was a confident and professional individual with a capacity to articulate and debate a point of view with evidence. The irony was that the employer consistently used this virtue negatively against the subject first covertly and then overtly in the statements of complaints. Examples of false assertion by the managers included that staff find the subject is aggressive, intimidating and putting the institution at risk!

The consequences of working under such a working environment are multi-dimension. First of all the effects on the subjects personal life can be categorised as individual and family. The individual effects include health, financial, career and family problems: the subject suffered mental and emotional stresses manifesting as physical and emotional symptoms. Quite apart from the emotional suffering, the combined effect of ill-health was debilitating, led to a loss of confidence, reduced output, and financial loss in fees for GP/consultant/psychiatrist/medicine. The effect on the subject's family was most unforgivable. The family also suffered severe emotional stress and ill-health which strained the relationship between the subject and the rest of the family leading to separation.

For the employer, it is the loss of an active dedicated employee who put institution goals ahead of personal objectives. Lost productivity. Lost progress. Lost market. Therefore, lost long-term investment and possible lost returns. Unnecessary expenditure in lawsuit(s) that could be invested in the institution for its staff and students' future.

DISCUSSION

Recommendations to combat bullying in the workplace are directed at the employer (16,23), e.g employers must educate their line managers, and should investigate claims thoroughly. By the end of the last century, most western governments acknowledged bullying and its consequences as a major problem, and have issued policy statements holding employers responsible for managing a stress-free working environment. This is no different to the executive/vice-chancellor's passing of the problems to the source of the problem to resolve! It is not, therefore, surprising that the number of cases post government legislations for stress-free working environment including this one (15,22-24) demonstrate that the offending employers continue to show a disregard for the law let alone implementing anti-harassment recommendations. The politicians, the trustees, the auditors, the legal community, staff, the community they all know who the offending organisations are – the question is why do we allow bullying behaviour to continue?

Clearly, it is not as easy to study perpetrators or organisations. Any references to the bully or organisation characteristics are usually obtained from the victims' accounts. Most studies

also rely on surveys of victims or legal/court case notes. However, very few cases make it to the courts and a majority accept out of court settlements (for obvious reasons e.g low levels of self-esteem, stressed and depressed, ill-health). However, the settlement comes with a gagging order preventing the victims from discussing any aspects of the case with anyone! Therefore, we know very little about the victims and in particular the effect on their families; the untold damage to health and mental well being in particular the emotional well-being of the children. In addition, our information on bullying is collected after the event; after a period of sustained bullying and stressful working environment. Thus, although the data set will have contained historical information it is essentially cross-sectional information on an individual exhibiting low self-esteem, uninterested, depressed and unable to articulate. It is not surprising that some authors recommend self-development training (e.g., assertiveness) models to combat bullying! This type of models accepts bullying in the workplace and places the onus on the employee to prepare for it.

In attempting to understand why certain senior managers who already hold positions of power and have established “empires” behave in such a manner in today’s society, the subject reported that almost all the comments received from other colleagues pointed to the insecurity and low confidence of the management due to their lack of experience. These comments appear in line with the literature quoted in the introduction. However, they do not explain the treatment of other teaching staff who did not pose a threat to anyone and simply wanted to do their jobs. One simple explanation could come from the literature. Such a management style is reminiscent of school yard/playground bullying. There is some evidence to suggest school bullies suffer from psychological and mental health problems which go undiagnosed and untreated (10,11), furthermore, school bullying may be transferred to adulthood and workplace (8). On the other hand legal risks may have influenced management behaviour. The literature provides examples of the legal precedent of employees being awarded damages against employers who failed to provide due care and support for appointing inexperienced staff into management roles (22).

An important issue arising from the case report and which did not feature in the literature is the effects on the victim’s family quality of life i) sudden change in the family, and ii) sustained strained family relationship and stress, and iii) the workforce as passive observers.

It is commendable to see that McAvoy and Murtagh (14) suggest that the medical profession ought to take a serious role in preventing bullying in the workplace. This would be a good idea if it wasn’t for the fact that health services have one of the highest rates of bullying. Denying that bullying or racism does not exist in ‘our society’ has never or will never resolve the issue. In the absence of solid evidence to explain the reasons for bullying, societies where bullying is common must acknowledge it rather than deny it and eradicate it from politics, home, school yards and the workplace. In other words, we cannot wait for a political solution and society must own and solve the bullying problem e.g., see Shahtahmasebi (27). As long as your manager believes that being a ‘team player’ means doing what you are told then bullying will be part of the culture.

Chapter 102

STUDENT BULLYING: OVERVIEW OF RESEARCH, FEDERAL INITIATIVES, AND LEGAL ISSUES*

Gail McCallion and Jody Feder

SUMMARY

Many Members of Congress have become increasingly concerned about what can be done to address student bullying. This concern has arisen in response to high-profile bullying incidents that have occurred in recent years, and due to a growing body of research on the negative consequences of school bullying.

Congress is interested in ensuring that schools are safe, secure places for students, so that they can receive the full benefits of their education. Several bills that address school bullying have already been introduced in the 113th Congress, although none has been enacted as of the date of this report.

Some of the research on anti-bullying programs has found mixed success, particularly in the United States. However, a meta-analysis of 44 evaluations identified particular characteristics of school-based bullying programs that may help reduce bullying.

This study found the intensity and duration of a program, as well as the number of program elements, to be linked with effectiveness. Other factors found to be important to effectiveness were parent training, parent meetings, firm disciplinary methods, classroom rules, classroom management, and improved playground supervision.

Currently, there is no federal statute that explicitly prohibits student bullying or cyber-bullying. Under some circumstances, however, bullying may be prohibited by certain federal civil rights laws. In addition, bullying may, in some instances, constitute a violation of state criminal or tort law.

There are several federal initiatives that are specifically focused on student bullying, including interagency initiatives. In addition, there are a variety of federal initiatives that are not solely or primarily focused on student bullying, but permit some funds to be used for this

* This is an edited, reformatted and augmented version of Congressional Research Service, Publication No. R43254, dated October 18, 2013.

purpose. Representatives from the U.S. Departments of Agriculture, Defense, Education, Health and Human Services, the Interior, and Justice, as well as the Federal Trade Commission and the White House Initiative on Asian Americans and Pacific Islanders, have formed a Federal Partners in Bullying Prevention Steering Committee. The Federal Partners work to coordinate policy, research, and communications on bullying topics. The Federal Partners have created a website, <http://www.stopbullying.gov>, which provides extensive resources on bullying, including information on how schools can address bullying.

Although there is currently no federal anti-bullying statute, there has been a surge in state legislation in recent years. A Department of Education (ED) study found that between 1999 and 2010, 120 bills and amendments to existing bills were introduced by states. Currently, 49 states have passed anti-bullying legislation. The majority of these laws direct school districts to adopt anti-bullying policies. However, the requirements placed on schools by these laws are quite varied. In addition, many of these laws do not contain all the key components of anti-bullying legislation that the U.S. Department of Education identified as important in a document it distributed to school districts.

INTRODUCTION

Significance for Congress

Many Members of Congress have become increasingly concerned about what can be done to address student bullying. Congressional interest is in response to high-profile incidents of bullying and their negative consequences, as well as to an increasing body of research documenting the detrimental effects of school bullying.¹

This has spurred interest in ensuring that schools are safe, secure places for students, so that they can receive the full benefits of their education. Several bills that address school bullying have been introduced in the 113th Congress, although none as of the date of this report have been enacted. However, currently 49 states have anti-bullying laws, although there is considerable variation in the content of these laws.²

Report Roadmap

This report begins with working definitions of bullying and cyber-bullying that were developed by a federal interagency working group. It provides a brief overview of research on the prevalence and impact of bullying, and it reviews research on what can be done to reduce student bullying. It discusses the responsibility of schools regarding bullying behavior; and it reviews the status of state laws that have been adopted to address student bullying. In addition, it discusses federal interagency initiatives intended to prevent bullying, and includes an appendix that summarizes many additional federal initiatives that permit some funding to be used for anti-bullying efforts. Finally, it discusses the legal issues and recent case law that define the parameters schools must consider in developing anti-bullying policies.

Definitions of Bullying and Cyber-Bullying

The Centers for Disease Control and Prevention (CDC) is leading an effort to develop a consensus definition of bullying that can be used throughout the school bullying research field.³ A consensus definition is key to obtaining consistent and comparable data on bullying. According to CDC health scientist Alana Vivolo-Kantor: “The lack of a uniform definition hinders our ability to understand the true magnitude, scope, and impact of bullying and track trends over time.

Consistent terminology with standardized definitions is necessary to improve public health surveillance of bullying and inform efforts to address bullying.”⁴ For the present, a federal working group has published working definitions of bullying and cyber-bullying (see text box below).

Bullying: Working Definitions

“Unwanted, aggressive behavior among school aged children that involves a real or perceived power imbalance.

The behavior is repeated, or has the potential to be repeated, over time. Both kids who are bullied and who bully others may have serious, lasting problems. In order to be considered bullying, the behavior must be aggressive and include:

- A Real or Perceived Imbalance of Power: Kids who bully use their power—such as physical strength, access to embarrassing information, or popularity—to control or harm others. Power imbalances can change over time and in different situations, even if they involve the same people.
- Repetition: Bullying behaviors happen more than once or have the potential to happen more than once.⁶
- Bullying includes actions such as making threats, spreading rumors, attacking someone physically or verbally, and excluding someone from a group on purpose.

Cyber-bullying is bullying that takes place using electronic technology. Electronic technology includes devices and equipment such as cell phones, computers, and tablets as well as communication tools including social media sites, text messages, chat, and websites.

Examples of cyber-bullying include mean text messages or emails, rumors sent by email or posted on social networking sites, and embarrassing pictures, videos, websites, or fake profiles.”⁷

Cyber-bullying is a relatively new form of bullying that has become a concern due to the increasing use of technology by students as a method of communicating with peers.

Cyber-bullying differs from traditional bullying because it can happen at any time of day or night, and messages can be immediately viewed by many others.

In addition, cyberbullying messages can be posted anonymously, and the victim may not know who the perpetrator is.

ESTIMATES OF THE PREVALENCE, PREDICTIVE FACTORS FOR, AND CONSEQUENCES OF BULLYING

Although this report focuses on bullying of students in grades K-12, it is worth noting that elementary and secondary students are not the only potential victims of bullying. Bullying also occurs at institutions of higher education (IHEs)⁸ and at workplaces, as well as other locations.

Students may be exposed to bullying at school for many reasons. Research indicates that although no single factor can explain bullying behavior, certain individuals are more vulnerable to being bullied, for example, those who have low self-esteem and are unpopular, friendless, or rejected.⁹ In addition, studies indicate that some students, including those with disabilities and those who are GLBT, are disproportionately subjected to bullying behavior.¹⁰ However, because bullying can happen to any student, some experts recommend that a school policy that enumerates groups protected by its anti-bullying policy also make clear that the requirements of the policy are not limited to those enumerated groups.¹¹

The number of research studies on student bullying has significantly increased in recent years. However, most studies on the prevalence and/or impact of bullying are not directly comparable for several reasons:

- the definition of bullying is not consistent across studies;¹²
- the age range of surveyed students varies;
- the time period for the analysis varies (e.g., bullying behavior in the last two months versus bullying behavior over a school year or lifetime exposure);
- the survey methodology varies; and¹³
- some studies provide an overall prevalence rate for bullying, while other studies separate bullying by type (e.g., physical, emotional, or electronic).

In addition, when negative outcomes are found to be associated with bullying, it is difficult to discern the extent to which the bullying behavior is responsible. One study on bullying states that

it is not entirely clear whether the connections between bullying, victimization, and psychosocial difficulties reflect causes, consequences, or merely concomitant correlates of bullying and/or victimization.¹⁴

Prevalence of Bullying

A Government Accountability Office (GAO) study examined four federal agency sponsored nationally representative surveys that include questions on student bullying: the National Youth Risk Behavior Survey (2011, YRBSS);¹⁵ the School Crime Supplement to the National Crime Victimization Survey (2012, SCS/NCVS);¹⁶ Health Behavior in School-aged Children (2005/2006, HBSC);¹⁷ and the National Survey of Children's Exposure to Violence (2008, NatSCEV).¹⁸ Due to differences across the surveys in definitions, the age of students surveyed, and the time frame of the studies, among other things, each survey obtained different estimates for the prevalence of bullying and cyber-bullying (or electronic bullying). Three of the surveys included an overall measure of the prevalence of bullying behavior. The overall

prevalence of bullying varied across the three surveys—from a low of 20.1% to a high of 27.8%. YRBSS estimated that 20.1% of surveyed youth reported being bullied; HBSC estimated that 27% of surveyed youth reported being bullied; and SCS/NCVS estimated that 27.8% of surveyed youth reported being bullied. In addition, all of the surveys included some measure of electronic bullying. The overall prevalence of electronic bullying varied across the four surveys—from a low of 1.8% to a high of 16.2%. NatSCEV estimated that 1.8% of surveyed youth reported Internet harassment; HBSC estimated that 8.1% of surveyed youth reported having been bullied using a computer or e-mail messages or pictures, and 5.7% reported having been bullied using a cell phone; SCS/NCVS estimated that 9% of surveyed youth reported being cyber-bullied; and YRBSS estimated that 16.2% of surveyed youth reported being electronically bullied. The surveys did not obtain consistent results on whether bullying was greater for one sex, race, or ethnic group. The surveys also varied in the extent to which they collected data on additional demographic characteristics on youth who were bullied.¹⁹

Student Bullying Research on the Precursors for, and Impacts of, Bullying

Many researchers who focus on student bullying believe that a variety of factors interact to influence bullying behavior, including “families, schools, peer groups, teacher-student relationships, neighborhoods, and cultural expectations.”²⁰ The interaction of these factors can have a positive influence on reducing bullying—if a positive school environment with involved, supportive adults and teachers is created, a positive peer culture is established, and school connectedness is reinforced. Researchers also note that bullying generally occurs with the physical or virtual presence of an audience of peers. These bystanders can play an important role in reinforcing bullying behavior through laughter or other encouragement, or in curbing it by speaking out against the behavior.

A 2010 meta-analysis of 153 studies evaluating predictors of being a bully, a victim, or bully-victim found some predictors were shared by both bullies and victims of bullying, including family environment, school climate, community factors, and poor social problem-solving skills. However, the authors found some factors to be more associated with one group than another. For example, bullies were more likely to have externalizing behaviors,²¹ poor academic performance, and negative thoughts or beliefs about others, and to be negatively influenced by their peers. Victims were more likely to have internalizing behaviors and negative thoughts about themselves, and to be rejected and isolated. Although both had deficits in social competence, bullies were generally more socially competent than victims.²²

In addition, some students engage in bullying behavior and are also a victim of bullying, either simultaneously, or by switching roles over time. These so called “bully-victims” were found to be the most at risk—containing risk factors associated with both of the other two groups:

That is, bully victims appeared to resemble victims by being rejected and isolated by their peers and to resemble bullies by being negatively influenced by the peers with whom they do interact.²³

As discussed above, both victims of bullying and those who engage in bullying behavior can experience psychological difficulties and social relationship problems. Additionally, a GAO literature review of seven meta-analyses on the impact of bullying on victims indicates that bullying may result in psychological, physical, academic, and behavioral issues.²⁴

Recent high profile suicides following incidents of bullying have heightened concerns about bullying behavior. The American Foundation for Suicide Prevention (AFSP) states that “Elevated rates of depression, suicidal ideation and suicide attempts have been found in youth who are bullied and also in those who bully others.”²⁵ However, AFSP indicates that no single factor is responsible for suicide. The factors that are correlated with suicide are multidimensional—for example, mental and developmental disorders, early life adverse events, and personality traits, among others. In addition, AFSP notes that “Suicidal ideation and suicide attempts occur in a small percentage of youth involved in bullying.”²⁶

EFFICACY OF ANTI-BULLYING PROGRAMS

Some of the research on anti-bullying programs has found mixed success from anti-bullying programs, particularly in the United States.²⁷ However, a cross-national meta-analysis of 44 evaluations identified particular characteristics of school-based bullying programs that may help reduce bullying.²⁸ The study found that on average, school-based anti-bullying programs decreased bullying behavior by 20%-23% and victimization by bullies by 17%-20%.

This study found the intensity and duration of a program, as well as the number of program elements, to be linked with effectiveness. Other elements found important to effectiveness were parent training, parent meetings, firm disciplinary methods, classroom rules, classroom management, and improved playground supervision. The study did not find evidence that working with peers was effective.²⁹ The authors also recommended that a system of accreditation for anti-bullying programs be established to help ensure that programs being adopted by schools include the elements that have been found to be effective.³⁰

Another study pointed out the importance of addressing peer norms in anti-bullying programs. In peer groups where bullying is the norm, the authors of the study argue that “Until these peer norms are modified, it is likely that bullying behaviors will remain intractable in our schools.”³¹

Resources for states and schools on effective anti-bullying programs are becoming more widely available. There has been an increased focus in recent years on the importance of school climate to preventing bullying and improving a variety of other school indicators. The National School Climate Center has published a resource that addresses the implementation of positive school climate practices as they relate to a variety of issues important for schools, including school bullying.³² In August 2008, ED published a document to assist schools in evaluating anti-bullying policies and practices titled *Effective Evidence-based Practices for Preventing and Addressing Bullying*.³³ In addition, several federal agencies maintain websites that include extensive information on anti-bullying programs that have proved effective or are promising.³⁴

STATE BULLYING LEGISLATION

As of the date of this report, 49 states have at least one anti-bullying law, although the content of these laws varies considerably. The majority of these laws direct school districts to adopt anti-bullying policies. However, the requirements placed on schools by these laws are quite varied.

In 2010, ED issued an in-depth report focused on state bullying laws.³⁵ The report noted the surge in state legislation addressing bullying in recent years, with 120 bills or amendments to existing legislation introduced between 1999 and 2010. According to the report, the landscape of state legislation has been changing as new bills (or amendments to existing laws) that address student bullying have been introduced that reflect:

the rapidly evolving political and policy environment surrounding bullying in schools, where lawmakers are continually refining legislative expectations for schools in response to the new problem dimensions (e.g., the growth of cyber-bullying), and to emerging research concerning effective policy strategies for combating student bullying.³⁶

The report's evaluation of the content and expansiveness of these laws highlighted the tremendous variation in these laws. The report was based on the 46 states that had bullying laws in place prior to the study. According to the report all but three of these states included definitions of what behaviors were prohibited. All but one of the 46 states required school districts in the state to adopt bullying policies. Forty-one of these states had developed model bullying policies, and 36 states included a prohibition on cyber-bullying or bullying using electronic media. In addition, 13 states included a provision stating that schools could address bullying that occurs outside of school grounds if it creates a hostile school environment.

The report delineated 11 key components of a comprehensive state anti-bullying statute.³⁷ The topics addressed by these 11 key components include the following:

- Purpose Statement
- Statement of Scope
- Specification of Prohibited Conduct
- Enumeration of Specific Characteristics
- Development and Implementation of Local Policies
- Review of Local Policies
- Communication Plan
- Training and Prevention Education
- Transparency and Monitoring
- Statement of Rights to Other Legal Recourse³⁸

The report classified each state's legislation into one of three categories for each key component on a continuum from least to most expansive and scored them from 0-2. Key components in more expansive state laws were usually more inclusive and more prescriptive, used less discretionary language, or established stronger measures of accountability. There was considerable variation across states in the number of the 11 key components included in state law, and in the level of detail and scope in the components that were included.³⁹ The report indicates that it did not include an analysis of how effectively school districts and individual

schools are implementing these anti-bullying policies. A second phase of the study will address implementation in a sample of school districts and schools:

While this report focuses on documenting and profiling policy across the states, these policies may not benefit schools or students unless they can be successfully implemented. For example, legislation that defines prohibited bullying behaviors, and specifies graduated and substantial sanctions, will often require extensive implementation procedures for the implementing of the sanction (e.g., expulsion). Whether these necessary actions are feasible within resource constraints cannot be determined through a policy review alone.⁴⁰

SCHOOL RESPONSIBILITIES REGARDING BULLYING

Schools must balance a variety of factors in developing policies to address bullying. Among other things, they must meet state, federal, and local regulations and statutory requirements.⁴¹ Although resources on factors to consider in developing a comprehensive school anti-bullying policy are becoming more widely available,⁴² developing and implementing comprehensive and effective bullying policies can be challenging for schools. As more schools adopt anti-bullying policies, a variety of potential policy issues have arisen—including the wide variation in the coverage provided by these policies, the potential difficulty in ensuring civil rights laws are not violated while simultaneously ensuring that constitutional protections on free speech are not impinged upon, and the particular difficulties of developing policies to address the rising phenomenon of cyber-bullying.

Focus on Cyber-Bullying

Although cyber-bullying frequently occurs off school grounds, it can have negative effects that are felt at school. Developing policies that address cyber-bullying can be a particular challenge for schools. School districts must deal with evolving case law on issues related to cyber-bullying that may cause uncertainty regarding a school's legal responsibility or potential culpability. For example, in some instances courts have prohibited disciplining a student for out of school speech. (See discussion of the Tinker standard under "Legal Issues.")

Cyber-bullying experts Sameer Hinduja and Justin Patchin recommend that schools ensure that their current policies on harassment and bullying permit disciplining students for cyber-bullying: They note that "If their policy covers it, cyber-bullying incidents that occur at school—or that originate off campus but ultimately result in a substantial disruption of the learning environment—are well within a school's legal authority to intervene."⁴³ The authors further note that

Even though the vast majority of these incidents can be handled informally (calling parents, counseling the bully and target, expressing condemnation of the behavior), there may be occasions where formal response from the school is warranted. This is particularly the case in incidents involving serious threats toward another student, if the target no longer feels comfortable coming to school, or if cyber-bullying behaviors continue after informal attempts to stop it have failed. In these cases, the authors suggest that detention, suspension, changes of placement, or even expulsion may be necessary. If these extreme measures are

required, it is important that educators are able to clearly demonstrate the link to school and present evidence that supports their action.⁴⁴

ED Dear Colleague Letter: School Responsibilities Regarding Bullying that Rises to the Level of Discriminatory Harassment

In December of 2010, the U.S. Department of Education issued a Dear Colleague Letter (DCL) that provided guidance on schools' responsibilities regarding bullying, in particular how some forms of bullying could rise to the level of discriminatory harassment, and as a consequence, might violate civil rights statutes. Several civil rights statutes explicitly protect against harassment based on race, color, national origin, sex, and disability. (See discussion of "Legal Issues.") Several of these laws are enforced by ED's Office for Civil Rights (OCR).⁴⁵ If a school or Institution of Higher Education fails to adequately address harassment of a student that falls under one of these protected categories, it has not met its statutory obligations to protect the student according to the DCL:

Harassment creates a hostile environment when the conduct is sufficiently severe, pervasive, or persistent so as to interfere with or limit a student's ability to participate in or benefit from the services, activities, or opportunities offered by a school. When such harassment is based on race, color, national origin, sex, or disability, it violates the civil rights laws that OCR enforces.... A school is responsible for addressing harassment incidents about which it knows or reasonably should have known.⁴⁶

Furthermore, according to the DCL, addressing the discriminatory harassment through a school's anti-bullying policy is not sufficient:

If an investigation reveals that discriminatory harassment has occurred, a school must take prompt and effective steps reasonably calculated to end the harassment, eliminate any hostile environment and its effects, and prevent the harassment from recurring. These duties are a school's responsibility even if the misconduct also is covered by an anti-bullying policy, and regardless of whether a student has complained, asked the school to take action, or identified the harassment as a form of discrimination.⁴⁷

Harassment Based on Disability

It is important to note that students with disabilities who are victims of bullying may be able to file a complaint under Section 504 of the Rehabilitation Act (Section 504), Title II of the American with Disabilities Act (Title II), and the Individuals with Disabilities Education Act (IDEA) in addition to pursuing redress through state anti-bullying laws, state civil rights legislation, other state laws, or in some circumstances through other federal civil rights legislation. This issue is addressed in an ED Dear Colleague letter issued on July 25, 2000. According to ED, state and school districts are required by Section 504, Title II, and IDEA to:

ensure that a free appropriate public education (FAPE) is made available to eligible students with disabilities. Disability harassment may result in a denial of FAPE under these statutes. Parents may initiate administrative due process procedures under IDEA, Section

504, or Title II to address a denial of FAPE.... In addition, an individual or organization may file a complaint alleging a violation of IDEA under separate procedures with the state educational agency.⁴⁸

A recent ED DCL provided more detailed guidance on the responsibility of schools to address bullying of students with disabilities:

Whether or not the bullying is related to the student's disability, any bullying of a student with a disability that results in the student not receiving meaningful educational benefit constitutes a denial of FAPE under IDEA and must be remedied.⁴⁹

The DCL also made clear that care must be taken in considering changing the placement of a student with a disability who is being bullied (i.e., the school must ensure that the student remains in the least restrictive educational environment in order to provide the student a FAPE).

Response to Dear Colleague Letter

Some groups have raised concerns about the guidance ED provided in its December 2010 Dear Colleague Letter. The National School Boards Association (NSBA) submitted a letter to ED stating that the guidance would place too broad an obligation on schools. According to the NSBA's letter:

our fear is that absent clarification, the Department's expansive reading of the law as stated in the DCL will invite misguided litigation that needlessly drains precious school resources and creates adversarial climates that distract schools from their educational mission.⁵⁰

In addition, the American Jewish Committee and the Religious Freedom Education Project/First Amendment Center issued proposed guidelines for school administrators intended to address bullying while also protecting students' freedom of speech and expression. Fifteen additional organizations signed on to these guidelines. The guidelines note that schools must balance safety concerns and free expression. They argue that unless student speech causes a substantial disruption at school it should not be censored.⁵¹

In response to these proposed guidelines the Anti-Defamation League (ADL) submitted a letter to ED calling them "ill-conceived, unnecessary, deeply flawed, and counterproductive to confronting the growing and serious problem of bullying and cyber-bullying."⁵² Furthermore, the ADL letter notes that

Bullying situations very rarely erupt as conflicts over political or religious speech.... Instead, they much more often involve the intentional targeting of an individual with less physical or social standing for physical or verbal abuse. Targeted students are in a very different power position than those who are doing the bullying. The aggressor's objective is not to convince his/her target of the rightness of a policy position—it is, rather, to cause physical or emotional harm.⁵³

FEDERAL AGENCY EFFORTS ON BULLYING

There are currently several federal initiatives that address student bullying. However, many of these initiatives are not solely or primarily focused on student bullying, but permit some funds to be used for this purpose. This section of the report summarizes interagency efforts to address student bullying. In addition, this report includes an Appendix that briefly summarizes selected federal bullying initiatives that may allow funding to be used to address school bullying. The Appendix focuses on some of the initiatives that have been undertaken by the three federal agencies that are most involved in addressing this issue: The U.S. Department of Education (ED), the U.S. Department of Health and Human Services (HHS), and the U.S. Department of Justice (DOJ). Note that bullying is often a small, optional part of the initiatives included in the Appendix. The initiatives that are included should not be viewed as an exhaustive list of federal initiatives that may address school bullying.

Interagency Initiatives

Representatives from the U.S. Departments of Agriculture, Defense, Education, Health and Human Services, the Interior, and Justice; the Federal Trade Commission; and the White House Initiative on Asian Americans and Pacific Islanders have formed a Federal Partners in Bullying Prevention Steering Committee. The Federal Partners work to coordinate policy, research, and communications on bullying topics. The Federal Partners have created a website, <http://www.stopbullying.gov>, which provides extensive resources on bullying, including information on how schools can address bullying.⁵⁴ In addition, with leadership from the U.S. Department of Education (ED), the Federal Partners have sponsored three anti-bullying summits attended by education practitioners, policymakers, researchers, and federal officials.⁵⁵ With ED and HHS, the CDC is currently leading an effort to develop a consensus definition of bullying that is intended to provide a consistent definition that will enhance comparability of data across studies and consequently lead to better measurement and tracking of bullying, as well as to improved prevention and responses to bullying.⁵⁶

Three agencies currently collaborate on a program called Safe Schools/Healthy Students (SS/HS). SS/HS is funded jointly by ED and HHS's Substance Abuse and Mental Health Services Administration (SAMHSA). The program is administered by ED, SAMHSA, and DOJ. Although SS/HS is not primarily an anti-bullying program, grantees may use program funds to include an anti-bullying component as part of their overall comprehensive plan of activities, programs, and services focusing on healthy childhood development and the prevention of violence and alcohol and drug abuse. SS/HS grants are awarded competitively to local educational agencies (LEAs). LEAs that receive a grant are required to establish partnerships with local law enforcement, public mental health, and juvenile justice agencies/entities.⁵⁷

Additionally, six agencies collaborated (U.S. Department of Education, U.S. Department of Health and Human Services, U.S. Department of Homeland Security, U.S. Department of Justice, Federal Bureau of Investigation, and the Federal Emergency Management Agency) to develop and publish comprehensive guides for developing high-quality emergency operations

plans. Three separate guides were published; each was targeted to a different audience—elementary and secondary schools, institutions of higher education, and houses of worship.⁵⁸

LEGAL ISSUES

Currently, there are no federal statutes that explicitly prohibit student bullying or cyberbullying. Under some circumstances, however, bullying in schools may be prohibited by certain federal civil rights laws. In contrast, many states have laws that explicitly prohibit bullying. In addition, bullying may, in some instances, constitute a violation of state criminal or tort law. The federal and state laws that govern traditional forms of bullying are described below, followed by a separate section that discusses federal and state laws that may pertain to cyberbullying.

Federal Law

Under certain circumstances, federal civil rights statutes may be used to combat bullying in schools. The applicable federal civil rights statutes that prohibit discrimination in schools include Title VI of the Civil Rights Act of 1964 (CRA), which prohibits discrimination on the basis of race, color, or national origin in federal funded programs or activities;⁵⁹ Title IX of the Education Amendments of 1972, which prohibits discrimination on the basis of sex in federally funded education programs or activities;⁶⁰ Section 504 of the Rehabilitation Act of 1973, which prohibits discrimination on the basis of disability in federally funded programs or activities;⁶¹ Title II of the Americans with Disabilities Act of 1990, which prohibits discrimination on the basis of disability by state or local governments;⁶² Title IV of the CRA, which bars discrimination in public schools on the basis of race, color, sex, religion, or national origin;⁶³ and the Equal Educational Opportunities Act, which prohibits states from denying equal educational opportunities based on race, color, sex, or national origin.⁶⁴ The latter two statutes were largely designed to combat segregation in public schools.

Discriminatory conduct under these statutes includes peer harassment if such harassment is sufficiently serious that it creates a hostile environment and if such harassment is encouraged, tolerated, not adequately addressed, or ignored by school employees. If the bullying conduct in question involved discrimination or harassment on the basis of race, color, national origin, sex, or disability under the above statutes, then it is prohibited by federal law. However, bullying that does not constitute discrimination on these grounds is not covered.

In 2010, ED issued guidance that discusses when student bullying or harassment may violate federal education anti-discrimination laws and that clarifies a school's obligation to combat such bullying or harassment.⁶⁵ The guidance includes a discussion of when bullying or harassment that targets lesbian, gay, bisexual, or transgender students may be a form of sex discrimination that violates Title IX, as well as a section that describes when bullying or harassment of students who share a particular religion may constitute national origin discrimination in violation of Title VI.

Although none of these civil rights statutes explicitly prohibits discrimination on the basis of sexual orientation or gender identity, there may, as ED's guidance notes, be instances in which such discrimination may also be a form of sex discrimination that violates Title IX.⁶⁶ In

the employment context, the Supreme Court has recognized that sex discrimination may encompass same-sex sexual harassment, meaning that sex discrimination is prohibited even if the harasser and victim are members of the same sex.⁶⁷ The Court has also ruled that gender stereotyping is a form of discrimination on the basis of sex.⁶⁸ Therefore, if a student who is gay or transgender is being harassed because of a failure to conform to gender stereotypes, such harassment is prohibited by Title IX. It is important to note, however, that Title IX prohibits sexual orientation or gender identity discrimination only when it constitutes a form of sex discrimination.⁶⁹ Thus, the statute does not prohibit all forms of sexual orientation or gender identity discrimination or harassment of students.⁷⁰

Likewise, although none of the civil rights statutes described above explicitly prohibits discrimination on the basis of religion, there may be instances in which such discrimination may also be a form of national origin discrimination that violates Title VI. According to ED, “harassment against students who are members of any religious group triggers a school’s Title VI responsibilities when the harassment is based on the group’s actual or perceived shared ancestry or ethnic characteristics, rather than solely on its members’ religious practices.”⁷¹ Thus, for example, Jewish, Muslim, or Sikh students who share a religious identity may be victims of national origin discrimination if they are being bullied or harassed due to actual or perceived ancestry or ethnicity.

State Law

State laws also offer some protection to victims of bullying. Indeed, some states have statutes that explicitly prohibit bullying,⁷² while all states have general criminal and tort laws that may, under certain circumstances, provide remedies to victims of bullying. For example, certain forms of bullying are likely to violate a state’s general laws against criminal assault and battery or other infractions such as disorderly conduct. Thus, bullies may incur penalties in states without explicit anti-bullying statutes and may even incur stiffer penalties under assault and battery statutes in states that also have anti-bullying laws.

Furthermore, tort law remedies, which allow bullying victims to sue on their own behalf, are available in all states. Tort law, which is created by both court decisions and statutory enactments, is generally intended to provide a mechanism by which individuals who have been injured can sue to recover damages. Tort law also serves as a deterrent to prevent similar injurious activities in the future. With regard to bullying, typical tort actions include intentional tort claims or negligent tort claims.

Lawsuits based on an intentional tort theory typically involve claims that fall into two categories: assault and/or battery. In general, assault claims involve fear of harmful or offensive touching, while battery claims involve actual harmful or offensive touching. Lawsuits based on a negligent tort theory generally involve claims against schools for failure to reasonably supervise students or employees or for failure to anticipate the wrongful conduct of such third parties. In order to succeed in such claims, plaintiffs must establish that the school owed them a duty of supervision, that the school breached that duty, that the breach was a foreseeable cause of an injury, and that an actual injury resulted.

Finally, it is important to note that many school districts and individual schools have anti-bullying policies that may be applicable.

Cyber-Bullying

Cyber-bullying, which generally refers to harassment occurring among school-aged children through the use of the Internet, may or may not overlap with bullying that occurs in schools. Depending on the circumstances, some or all of the federal and state laws discussed above may apply to cyber-bullying. In addition, several states have passed legislation to prohibit cyberbullying. In many cases, such legislation requires or authorizes school districts to adopt cyberbullying policies.⁷³

It is important to note that the types of laws that may be invoked to combat cyber-bullying will vary depending on the circumstances of the particular case and thus may not be limited to the statutes cited above.⁷⁴

Constitutional Considerations

As noted above, there may be constitutional principles that limit the authority of federal, state, or local governments or schools from enacting anti-bullying laws and policies. These constitutional considerations primarily involve the First and Fourteenth Amendments.

First Amendment: Freedom of Speech

The First Amendment declares that “Congress shall make no law ... abridging the freedom of speech.” The Fourteenth Amendment’s due process clause imposes the same restriction upon the states,⁷⁵ many of whose constitutions have a comparable limitation on state legislative action.⁷⁶ Although the First Amendment guarantees free speech, the right is not absolute. Governments impose limitations on many types of speech, and courts frequently distinguish between constitutionally protected speech and other less socially valuable categories of speech. One such example of unprotected speech is speech that constitutes a true threat.⁷⁷ The Supreme Court has decided several “true threat” cases that provide the constitutional parameters that states or localities must meet when seeking to establish anti-bullying laws or policies.

In *Watts v. United States*,⁷⁸ the Court held that only “true threats” are outside the scope of the First Amendment. In *Watts*, the defendant attended a political rally and made the statement, “I have already received my draft classification ... I am not going. If they ever make me carry a rifle the first man I want to get in my sights is [President] L.B.J.”⁷⁹ The defendant was arrested and charged with violating 18 U.S.C. Section 871(a) for “knowingly and willfully ... [making a] threat to take the life of or to inflict bodily harm upon the President of the United States.” The Court held that, although the federal statute was not unconstitutionally overbroad, the defendant’s statement was protected because it was not a “true threat.” The Court found that the content of Watts’s statement, the context in which the statement was made, and the audience’s reaction⁸⁰ to the statement were all supportive of Watts’s claim that he engaged in protected “political hyperbole.”⁸¹ The Court recognized that “true threats” should not be afforded First Amendment protection, and stated, “What is a threat must be distinguished from what is constitutionally protected speech.”⁸²

Watts did not establish a bright-line test for distinguishing a true threat from protected speech. As such, lower courts have created varying tests for determining whether speech rises to the level of a true threat.⁸³ The main point of contention among the appellate courts is whether the focus of a “true threat” test should be on the speaker or the listener. Some courts evaluate

the existence of a threat by determining whether the speaker should reasonably have foreseen his words to be threatening,⁸⁴ while others rest the determination on whether a reasonable recipient would be threatened by the statement.⁸⁵

Based on these principles, it is possible that anti-bullying laws or policies could be deemed constitutionally deficient if the prohibited behavior does not rise to the level of a “true threat” under most circumstances. This analysis, however, may differ depending on whether the challenged language is contained in a state statute or school policy.

In the school context, school officials who use anti-bullying policies to take disciplinary action against students may face legal challenges based on the First Amendment. While students generally retain the protections of the First Amendment, these protections may not always mirror the constitutional protections afforded in other contexts.⁸⁶ For example, in *Tinker v. Des Moines Independent Community School District*,⁸⁷ the Court held that student expression may be regulated only if it would substantially disrupt school operations or interfere with the rights of others.⁸⁸

In *Tinker*, students wore black armbands to school to protest the United States’ involvement in Vietnam, despite knowledge that such action was in violation of school policy. The students were asked to remove the armbands, and upon their refusal were suspended until they came to school without the armbands. The Court held that the wearing of armbands for the purpose of expressing different viewpoints is the type of symbolic act within the protection of the First Amendment. Specifically, the Court ruled that “First Amendment rights, applied in light of the special characteristics of the school environment, are available to teachers and students. It can hardly be argued that either students or teachers shed their constitutional rights to freedom of expression at the schoolhouse gate.”⁸⁹

The Court subsequently refined the *Tinker* rationale as it applies to verbal expression or “pure speech.” In *Bethel School District 403 v. Fraser*,⁹⁰ the Court ruled that school officials had the authority to discipline a student for violating school rules by delivering a lewd speech at a school assembly. Shifting its focus from the students’ rights articulated in *Tinker*, the Court instead emphasized the school’s duty to inculcate habits and manners of civility and teach students the boundaries of socially appropriate behavior.⁹¹ In addition, the Court noted the importance of protecting minors from vulgar, lewd, or indecent language.⁹² As such, the Court concluded that the nomination speech had a disruptive effect on the education process, and that it was up to school officials to determine what manner of speech in the classroom or in school assembly is appropriate.⁹³

While it is undisputed that the First Amendment does not protect “offensive” speech while on school grounds, courts are less clear when the speech occurs off school premises. For example, in *iS. v. Bethlehem Area School District*,⁹⁴ an 8th grader created a website that contained derogatory remarks regarding a math teacher and a principal. Most of the website was devoted to ridiculing the math teacher, comparing her to Adolph Hitler and making fun of her physical appearance. In addition, the site contained a solicitation for contributions to pay for a “hit man.”⁹⁵ School officials subsequently expelled the student, citing the extreme emotional distress suffered by the math teacher and the disruption the website caused at the school. The student argued that his website was protected speech.

In reviewing the case, the Pennsylvania Supreme Court decided two issues: (1) whether the student’s speech constituted a true threat; and (2) whether the *Tinker* and *Fraser* standards permit a school district to discipline a student for off-campus speech. In addressing the “true threat” issue, the court determined that, although the website was in extremely poor taste, it

was not a “true threat.” Specifically, the court stated that “[w]e believe that the [w]ebsite, taken as a whole, was a sophomoric, crude, highly offensive and perhaps misguided attempt at humor or parody. However, it did not reflect a serious expression of intent to inflict harm,” as the site focused primarily on the teacher’s physical appearance, utilizing cartoons, hand drawings, and a reference to Adolph Hitler.⁹⁶

The court then addressed whether First Amendment jurisprudence permitted the school to discipline a student for off-campus speech. It dismissed the argument that the website was off-campus speech beyond the school’s jurisdiction. Specifically, the court stated that “[w]e find there is a sufficient nexus between the [w]ebsite and the school campus to consider the speech as occurring on-campus.”⁹⁷ The court made this determination because the student had accessed the site at school, showed it to a fellow student, and informed other students about the site.⁹⁸ The court then reasoned that school officials could punish the student under the *Tinker* or *Fraser* standard⁹⁹—under the *Fraser* standard because the speech on the website was vulgar and highly offensive,¹⁰⁰ and under the *Tinker* standard inasmuch as the website caused a substantial disruption of school activities.¹⁰¹

Ultimately, court rulings in this area tend to depend on the circumstances that arise in a given case, with courts sometimes upholding a school’s disciplinary actions¹⁰² and other times ruling in favor of a student’s right to free speech.¹⁰³

Fourteenth Amendment: Due Process

Another constitutional constraint that legislators and school administrators may face when drafting legislation or school policies aimed at curtailing bullying is the Fourteenth Amendment. The Fourteenth Amendment’s due process clause provides that “[n]o State shall ... deprive any person of life, liberty, or property, without due process of law....” Under the due process clause, criminal statutes that lack sufficient definiteness or specificity may be held “void for vagueness.” A governmental regulation or statute may be declared void if it fails to give a person adequate warning that his or her conduct is prohibited or if it fails to set out adequate standards to prevent arbitrary and/or discriminatory enforcement.¹⁰⁴

Indeed, a statute may be so vague or threatening to constitutionally protected activity that it can be pronounced unconstitutional on its face. For example, in *Papachristou v. City of Jacksonville*,¹⁰⁵ a unanimous Court struck down as facially invalid a vagrancy ordinance that punished:

dissolute persons who go about begging, ... common night walkers, ... common railers and brawlers, persons wandering or strolling around from place to place without any lawful purpose or object, habitual loafers, ... persons neglecting all lawful business and habitually spending their time by frequenting houses of ill fame, gaming houses, or places where alcoholic beverages are sold or served, persons able to work but habitually living upon the earnings of their wives or minor children.¹⁰⁶

The Court found the statute facially invalid, as it failed to provide fair notice or require specific intent to commit an unlawful act. The Court concluded that the statute permitted arbitrary and erratic arrests and convictions, provided police officers too much discretion, and criminalized activities that are normally innocent.¹⁰⁷

When evaluating the constitutionality of anti-bullying laws or policies, the courts may apply these due process principles. For example, in *Flaherty v. Keystone Oaks School*

District,¹⁰⁸ a student filed a lawsuit after being disciplined for posting on an online message board devoted to high school volleyball. A federal district court held that the breadth of student handbook policies pertaining to discipline and technology was overreaching, thus violating students' free speech rights. In addition, the court held that the policies were unconstitutionally vague in definition and as applied.

The court found the school policies unconstitutionally overbroad for several reasons. First, the policies were not referred to or incorporated in the student handbook. In addition, the policy "authorizes discipline where a student's expression that is abusive, offending, harassing, or inappropriate, interferes with the educational program of the schools." This standard, concluded the court, did not comply with the *Tinker* requirement that discipline should be reserved for those circumstances that cause a substantial disruption to school operations.¹⁰⁹

Finally, the court noted that even if it did not find the policy overbroad, it would find the student handbook policies unconstitutionally vague, as the terms "abuse, offend, harassment, and inappropriate" were not defined in any significant manner. In addition, the court found the policies not only vague in definition but also in application. The court noted that school personnel had varying interpretations of the policies. As such, the court concluded that the policies were vague enough to result in arbitrary enforcement. Therefore, the court concluded that the student handbook policies did not provide the student with adequate warning of proscribed conduct.

Ultimately, when drafting legislation or school policies to combat student bullying, legislators and school administrators must consider the constitutional constraints imposed by the First and Fourteenth Amendments. Specifically, such officials must ensure that statutes and school policies are narrow enough not to infringe upon protected speech and specific enough not to be found unconstitutionally vague.

APPENDIX.

Table A-1. Federal Agency Initiatives that May Address School Bullying

Title	Description	Federal Agency Administering Initiative
	<i>GRANT PROGRAMS</i>	
<i>The Safe and Drug Free Schools and Community Act (SDFSCA)</i>	SDFSCA is the federal government's primary program aimed at preventing drug abuse and violence, including student bullying, in and around public schools. ^a	Office of Elementary and Secondary Education, Office of Safe and Health Students, U.S. Department of Education
<i>Secure our Schools Program (SOS)</i>	SOS funds can be used for anti-bullying initiatives, among other things. Grants under this program provide funding to state, local, or tribal governments working in partnership with public schools to improve school safety. ^b	Office of Community Oriented Policing, U.S. Department of Justice
<i>Academic Centers of Excellence (ACE)</i>	The ACE program supports grants for National Academic Centers of Excellence in Youth Violence Prevention and Urban Partnership Academic Centers of Excellence. It funds collaborative efforts between research universities	Centers for Disease Control and Prevention, U.S. Department of Health and Human Services

Table A-1. (Continued)

Title	Description	Federal Agency Administering Initiative
<i>Academic Centers of Excellence (ACE)</i>	and community-based organizations to help community partners develop, implement, and evaluate comprehensive youth violence prevention efforts. ^c	Centers for Disease Control and Prevention, U.S. Department of Health and Human Services
<i>Juvenile Accountability Block Grant (JABG)</i>	The JABG program authorizes the Attorney General to make grants to states and units of local government to strengthen their juvenile justice systems and to foster accountability within their juvenile populations. The program focuses resources on holding juveniles accountable for their actions and building up the juvenile justice system in the states. ^d	Office of Justice Programs, Office of Juvenile Justice and Delinquency Prevention, U.S. Department of Justice
<i>Garrett Lee Smith State, Tribal, and Campus Youth Suicide Prevention Programs</i>	Grants made under this program help states, tribes, and campuses develop and implement youth suicide prevention and early intervention strategies involving public-private collaborations among youth-serving institutions. ^e	Substance Abuse and Mental Health Services Administration, U.S. Department of Health and Human Services
<i>Native Aspirations Grants</i>	Grants under this program fund training and technical assistance to provide proactive mental health assistance to children, youth, and their families living on American Indian Tribal reservations and in Alaska Native villages. The program is designed to help decrease the risk factors that contribute to youth violence, bullying, and suicide, and to help increase the protective factors linked to healthy, safe children and families. ^f	Substance Abuse and Mental Health Services Administration, U.S. Department of Health and Human Services
<i>School Crime Supplement to the National Crime Victimization Survey (SCS/NCVS)</i>	This survey is co-designed by the U.S. Department of Education and U.S. Department of Justice. It is a national survey of students ages 12-18 in public and private K-12 schools. SCS/NCVS collects information about victimization, crime, and safety at school, including bullying. It is currently administered every two years. ^g	Office of Justice Programs, Bureau of Justice Statistics, U.S. Department of Justice National Center on Education Statistics, U.S. Department of Education
<i>Civil Rights Data Collection (CRDC)</i>	The most recent (SY2009-SY2010) data collection is the first time the survey has included reporting on bullying and harassment (at both the school and district level). The survey also includes data on corporal punishment; in- and out-of-school suspensions, expulsions, zero tolerance expulsions, referral to law enforcement; and school-based arrests. This survey is based on a sample of public school districts and schools. It is conducted every two years. ^h	Office for Civil Rights, U.S. Department of Education

Title	Description	Federal Agency Administering Initiative
<i>Youth Risk Behavior Surveillance System (YRBSS)</i>	YRBSS monitors alcohol, tobacco, and drug use, sexual behaviors that lead to unintended pregnancy and sexually transmitted diseases, behaviors that lead to unintentional injury and violence, unhealthy dietary habits, and inadequate physical activity. It includes questions on student bullying. Students in grades 9-12 are surveyed every two years during the spring school semester. ⁱ	Centers for Disease Control and Prevention, U.S. Department of Health and Human Services
DATA COLLECTION		
<i>Health Behavior in School- Aged Children (HBSC)</i>	NICHHD conducts research on bullying through the Health behavior in School-Aged Children survey. This international survey includes a nationally representative sample of U.S students in grades 6-10, and includes questions addressing bullying behaviors (perpetration and victimization). This survey is conducted every four years. ^j	National Institute of Child Health and Human Development, National Institutes of Health, U.S. Department of Health and Human Services
<i>National Survey of Children's Exposure to Violence (NatSCEV)</i>	Surveys past-year and lifetime exposure to violence, including bullying, of children age 17 and younger. This phone survey is conducted periodically, based on a nationally representative sample of children. Children ages 10 and over are surveyed directly; responses for children under the age of 10 are obtained from their principal caregiver. ^k	Office of Justice Programs, Office of Juvenile Justice and Delinquency Prevention, U.S. Department of Justice Centers for Disease Control and Prevention, U.S. Department of Health and Human Services
<i>School Survey on Crime and safety (SSOCS)</i>	SSOCS is a survey of approximately 3,500 principals in public K-12 schools. SSOCS is ED's primary source of data on crime and safety at the school level. SSOCS includes questions on the reported frequency of bullying and cyber-bullying. It is currently administered every two years. ^l	National Center on Education Statistics, Institute of Education Sciences, U.S. Department of Education
RESOURCES ON PROMISING PRACTICES, PREVENTION, AND INTERVENTIONS		
<i>Measuring Bullying Victimization, Perpetration, and Bystander Experiences</i>	Compendium of bullying measurement tools. ^m	Centers for Disease Control and Prevention, U.S. Department of Health and Human Services
<i>Blueprints for Healthy Youth Development</i>	Identifies evidence-based prevention and intervention programs. ⁿ	Centers for Disease Control and Prevention, U.S. Department of Health and Human Services
<i>National Registry of Evidence- based Programs and Practices</i>	SAMHSA maintains a National Registry of Evidence Based Programs and Practices that includes bullying prevention programs. ^o	Substance Abuse and Mental Health Services Administration, U.S. Department of Health and Human Services

Table A-1. (Continued)

Title	Description	Federal Agency Administering Initiative
RESOURCES ON PROMISING PRACTICES, PREVENTION, AND INTERVENTIONS		
<i>Model Programs Guide</i>	This guide helps users select evidenced-based prevention and intervention programs. It allows users to search for programs based on criteria that they select, e.g., program type, target setting (such as schools), problem behavior (such as bullying), special populations, as well as by gender, race/ethnicity, and age. ^p	Office of Juvenile Justice and Delinquency Prevention, Office of Justice Programs, U.S. Department of Justice
<i>Community Action Planning</i>	Bullying prevention training modules and a community action toolkit to provide communities with research-based strategies to address bullying. ^q	Health Resources and Services Administration, U.S. Department of Health and Human Services
	OUTREACH	
<i>Stop Bullying Now Campaign</i>	The Stop Bullying Now Campaign is targeted to children ages 9-13. It has distributed resources on bullying to all public elementary and secondary schools and many other organizations that serve youth. ^r	Health Resources and Services Administration, U.S. Department of Health and Human Services
<i>Striving to Reduce Youth Violence Everywhere (STRYVE)</i>	STRYVE provides training and resources to achieve the goals of the program, which are to (1) increase awareness that youth violence can and should be prevented, (2) promote the use of youth violence prevention approaches that are based upon the best available evidence, and (3) provide guidance to communities on how to prevent youth violence. ^s	Centers for Disease Control and Prevention, U.S. Department of Health and Human Services
<i>Defending Childhood</i>	DOJ is leading this initiative, which is focused on children's exposure to violence. The initiative is working to coordinate resources in order to prevent, reduce, and better understand this issue. It provides funds for research, evaluation, and public awareness, as well as for demonstration grants. Although this is a broad initiative focusing on a comprehensive approach to violence, victimization through bullying may be included as one of the issues addressed. ^t	U.S. Department of Justice
	REPORTS/RESEARCH ON SCHOOL BULLYING	
<i>State Bullying Laws and Policies</i>	The U.S. Department of Education has published a detailed report on state bullying laws that is available online. ^u	Office of Planning, Evaluation and Policy Development, Policy and Program Studies Services, U.S. Department of Education
<i>Reports</i>	The CDC has published several reports on school bullying including three on electronic aggression— including one targeted to researchers and one targeted to caregivers. ^v	Centers for Disease Control and Prevention, U.S. Department of Health and Human Services

Title	Description	Federal Agency Administering Initiative
<i>Reports</i>	OJP has issued a series of publications on student bullying including some focused on peer victimization, and others on the impact of bullying on student behaviors, such as <i>student</i> engagement, attendance, and achievement. ^w	Office of Justice Programs, U.S. Department of Justice
<i>School-Based Programs to Reduce Bullying and Victimization</i>	This report reviews school-based programs to reduce bullying and victimization. ^x	National Criminal Justice Reference Service, Office of Justice Programs, U.S. Department of Justice
<i>Research</i>	Supports research to enhance the evidence base on bullying for use in program development at the school and district levels. Also supports research on the causes of violent and aggressive behaviors and the mechanisms underlying these behaviors. ^y	National Institute of Child Health and Human Development, National Institutes of Health, U.S. Department of Health and Human Services
	<i>TECHINICAL ASSISTANCE</i>	
<i>Technical Assistance Center on Positive Behavioral Interventions and Supports</i>	The Center provides capacity-building information and technical assistance to schools, districts, and states who are implementing School-wide Positive Behavioral Interventions and Supports (PBIS), including PBIS for bullying prevention. PBIS is a three-tiered prevention based approach to improving school-wide disciplinary practices. According to the Center, PBIS is used in more than 9,000 schools across 40 states. ^z	Office of Special Education, U.S. Department of Education
<i>National Training and Technical Assistance Center</i>	The Center provides technical assistance on student bullying, among other things. In addition, it provides funding for the Safe Start Initiative, which is intended to broaden the knowledge of, and promote community investment in, evidence-based strategies for reducing the impact of children's exposure to violence. ^{aa}	Office of Juvenile Justice and Delinquency Prevention, Office of Justice Programs, U.S. Department of Justice

Source: Compiled by CRS.

^a As authorized, the SDFSCA is divided into two major programs: State Formula Grants and National Programs. However, FY2009 was the last year that funding was provided for State Formula Grants. Overall funding for SDFSCA was considerably lower in FY2012 than it was in years when the State Grant Program also received funding. The SDFSCA program received a total of \$65 million in funding in FY2012. In contrast, for FY2009, the last year in which State Formula Grants received funding, the total funding for SDFSCA equaled \$435 million—\$295 million for State Formula Grants, and \$140 million for National Programs. For more information on the SDFSCA program see CRS Report RL34496, *Safe and Drug-Free Schools and Communities Act: Program Overview and Reauthorization Issues*, by Gail McCallion.

^b <http://www.cops.usdoj.gov/default.asp?Item=2368>.

^c <http://www.cdc.gov/violenceprevention/ace/>.

^d The only core mandate of the JABG program is that states must begin to implement a system of graduated sanctions for juveniles in order to be eligible for funding. As currently comprised, the program authorizes funding for 17 accountability based purpose areas. While not all of the purpose areas address activities in the school arena, one such purpose area is “establishing and maintaining accountability-based programs that are designed to enhance school safety, which programs may include research-based bullying, cyber-bullying, and gang prevention programs.” (42 USC 3796ee(b)(13)). <http://www.ojjdp.gov/programs/ProgSummary.asp?pi=1>.

^f See p. 300 of HHS FY2014 Budget Justification: http://www.samhsa.gov/Budget/FY2014/SAMHSA_FY2014_CJ_FINAL.pdf.

^g Although some of the data elements collected in this survey are available by state, bullying is not. The survey asks about school related topics such as alcohol and drug availability; fighting, bullying, and hate-related behaviors; fear and avoidance behaviors; gun and weapon carrying; and gangs at school. This survey is conducted every two years. Each incident of crime against an individual is counted as a victimization. However, if a particular student reports two incidents of victimization during the previous 6 months, then this student would be counted only once in the overall prevalence (“any”) estimate. Thus the prevalence indicates the number of students affected by victimization rather than the number of victimizations that occur at school. <http://nces.ed.gov/programs/crime/surveys.asp>.

^h The purpose of this survey is to monitor the extent to which public elementary and secondary schools are meeting their obligation to provide equal educational opportunities to all students. Most of the data are broken down by sex, race, ELL, IDEA, and Section 504 status. The most recent survey is based on a sample that covers more than 72,000 schools in approximately 7,000 school districts, and represents about 85% of all U.S. students. <http://ocrdata.ed.gov>.

^j <http://www.hbsc.org/about/index.html>.

^k <http://www.ojjdp.gov/pubs/235394.pdf>.

^l SSOCs collects data from school principals on: the frequency and types of crimes occurring at school, disciplinary actions allowed and used in schools, policies and practices designed to prevent or reduce crime in schools, and characteristics of school climate related to safety. It includes information on the percentage of schools reporting incidents of hate crimes and cyber-bullying. Since 2003, it has been administered every two years. <http://nces.ed.gov/pubs2011/2011320.pdf>.

End Notes

¹ See discussion of Student Bullying Research.

² The U.S. Department of Education has issued a report analyzing state bullying laws and policies that is available online: <http://www2.ed.gov/rschstat/eval/bullying/state-bullying-laws/state-bullying-laws.pdf>.

³ A uniform definition will be addressed in a forthcoming document titled: *Bullying Surveillance Among Youth: Uniform Definitions and Recommended Data Elements*, Version 1.0. Centers for Disease Control and Prevention, Public Health Law News: Office for State, Tribal, Local, and Territorial Support, October 2012.

⁴ Vivolo-Kantor also points out that “important factors need to be considered when drafting this definition. First and foremost, we felt it was important to develop a definition that leads to accurate measurement of bullying and that can be easily understood by the field. Second, we needed to make the definition relevant for schools but also for youth. Lastly, we needed to acknowledge that this definition was developed for surveillance purposes. Additional work is needed to translate the definition for use in other contexts, such as state or school bullying policies.”

⁵ <http://www.stopbullying.gov>.

- ⁶ <http://www.stopbullying.gov/what-is-bullying/definition/index.html#types>. In addition the website states that “It is not bullying when two kids with no perceived power imbalance fight, have an argument, or disagree. Conflict resolution or peer mediation may be appropriate for these situations.”
- ⁷ <http://www.stopbullying.gov/cyber-bullying/index.html>.
- ⁸ According to <http://www.stopbullying.gov>: “Although media reports often call unwanted, aggressive behavior among young adults ‘bullying,’ this is not exactly accurate. Many state and federal laws address bullying-like behaviors in this age group under very serious terms, such as hazing, harassment, and stalking. Additionally, most young adults are uncomfortable with the term bullying—they associate it with school-aged children.”
- ⁹ David P. Farrington and Maria M. Ttofi, “How to Reduce School Bullying,” *Victims and Offenders*, vol. 4 (2009), pp. 321-326.
- ¹⁰ Although there are no federal data surveys on bullying of students with disabilities; and gay, lesbian, bisexual and transsexual (GLBT) students (or those perceived to be GLBT), some research studies indicate that these students are frequent targets of bullying. See <http://www.stopbullying.gov/at-risk/groups/lgbt/#additional>, and <http://www.stopbullying.gov/at-risk/groups/special-needs/BullyingTipSheet.pdf>. Recent guidance from ED addresses the bullying of students with disabilities in detail. See http://www.ed.gov/blog/2013/08/keeping-students-with-disabilities-safe-from-bullying/?utm_medium=email&utm_source=govdelivery.
- ¹¹ See http://www.huffingtonpost.com/deborah-temkin/the-three-words-missing-f_b_3480347.html. In addition, research has indicated that bullying occurs not only to vulnerable youth, but also can occur when more popular youth bully lower ranking individuals within their peer group as a means to attain higher social status. Robert Faris and Diane Felmlee, “Status Struggles: Network Centrality and Gender Segregation in Same- and Cross-Gender Aggression,” *American Sociological Review*, vol. 76, no. 1 (February 2011), pp. 48-67.
- ¹² Studies also employ different terminology for “bullying” including bullying, peer victimization, peer abuse and relational aggression, among others.
- ¹³ Among other differences, most are based solely on self-reports. However, some studies are based on other sources of data, e.g., teacher ratings, direct observation, peer-nominations.
- ¹⁴ Susan Swearer, et al., *What Can Be Done About School Bullying? Linking Research to Educational Practice*, *Educational Researcher*, Vol. 39, No 1, (Jan/Feb 2010), p. 38.
- ¹⁵ Since the issuance of the GAO report, YRBSS has been updated with data for the period of September 2010–December 2011. These updated data are used here. *Youth Risk Behavior Surveillance—United States, 2011*, U.S. Department of Health and Human Services, Centers for Disease Control and Prevention.
- ¹⁶ Since the issuance of the GAO report, SCS/NCVS has been updated with bullying data for 2011. These updated data are used here. Robers, S., Kemp, J., and Truman, J. (2013). *Indicators of School Crime and Safety: 2012* (NCES 2013-036/ NCJ 241446). - ¹⁷ <http://www.hbsc.org/about/index.html>.
- ¹⁸ U.S. Government Accountability Office, *School Bullying: Extent of Legal Protections for Vulnerable groups Needs to Be More Fully Assessed*, GA0-12-349, May 2012, pp. 40-41, <http://www.gao.gov/assets/600/591202.pdf>. Two additional surveys that do not obtain survey data through student interviews are not included in this discussion, but are included in Appendix A. They are the Survey of School Crime and Safety (SSOCS), and the Civil Rights Data Collection (CRDC).
- ¹⁹ The School Crime Supplement to the National Crime Victimization Survey did, however, collect data on whether a student was the target of a “hate-related word” based on their race, ethnicity, religion, disability, gender, or sexual orientation.
- ²⁰ This approach to analyzing behavior is referred to as a social-ecological framework. It incorporates the interconnected personal, social, environmental, and societal factors that influence behavior. Susan Swearer, et al., *What Can Be Done About School Bullying? Linking Research to Educational Practice*, *Educational Researcher*, Vol. 39, No. 1, (Jan/Feb 2010), p. 43.
- ²¹ “Externalizing behavior problems—behaviors characterized by an undercontrol of emotions—include difficulties with interpersonal relationships and rule breaking as well as displays of irritability and belligerence ... conversely, internalizing behavior problems—defined as an overcontrol of emotions—include social withdrawal, demand for attention, feelings of worthlessness or inferiority, and dependency.” Guttmannova, et al., “Internalizing and Externalizing Behavior Problem Scores: Cross-Ethnic and Longitudinal Measurement Invariance of the Behavior Problem Index,” 2007 Sage Publications.
- ²² Clayton R. Cook et al., “Predictors of Bullying and Victimization in Childhood and Adolescence: A Meta-analytic Investigation,” *School Psychology Quarterly*, vol. 25, no. 2 (2010), p. 78.

- ²³ Clayton R. Cook et al., "Predictors of Bullying and Victimization in Childhood and Adolescence: A Meta-analytic Investigation," *School Psychology Quarterly*, vol. 25, no. 2 (2010), p. 78. Another meta-analysis of student bullying programs identified the following characteristics of bullies and victims of bullies: "Bullies tend to have poorer academic skills and grades than the majority of their classmates, often are lacking in the characteristic of empathy, and may have cognitive distortions and social perception biases related to perceived threats in their environment and with respect to how aggression is viewed as an effective way to solve problems. Bullies also tend to be at heightened risk for substance abuse and later criminal behavior, and are likely to become increasingly unpopular with peers as they get older, and tend to come from homes where there is poor parental role modeling in the form of coercive and aggressive means of problem solving and a lack of consistent and effective discipline. Bullying victims, on the other hand ... tend to be physically smaller or weaker in some way than perpetrators, and are often anxious, fearful, insecure, depressed, and have poor self-esteem. A high percentage of victims tend to engage in school avoidance behaviors, and many repeated victims of bullying at school end up dropping out of the school system. Victims are also more likely than perpetrators to bring weapons to school, for the purpose of revenge." Kenneth W. Merrell et al., "How Effective Are School Bullying Intervention Programs? A Meta-Analysis of Intervention Research," *School Psychology Quarterly*, vol. 23, no. 1 (2008), p. 27.
- ²⁴ U.S. Government Accountability Office, *SCHOOL BULLYING: Extent of Legal Protections for Vulnerable groups Needs to Be More Fully Assessed*, GA0-12-349, May 2012, pp. 8-10, <http://www.gao.gov/assets/600/591202.pdf>.

- ⁷¹ United States Department of Education, *Office for Civil Rights*, *Dear Colleague Letter*, October 26, 2010, <http://www2.ed.gov/about/offices/list/ocr/letters/colleague-201010.html>.
- ⁷² The Department of Health and Human Services maintains a website that seeks to combat bullying. The website also tracks state anti-bullying laws at <http://www.stopbullying.gov/laws/index.html>.
- ⁷³ For example, in Arkansas, cyber-bullying was added to the schools’ anti-bullying policies and included in provisions for school officials to punish students for some off-campus activities “if the electronic act is directed specifically at students or school personnel and is maliciously intended for the purpose of disrupting school and has a high likelihood of succeeding in that purpose.” However, it should be noted that some of these policies are limited in their application. For example, in Washington, the school district harassment prevention policies are applicable only to actions that take place “while on school grounds and during the day.” In other words, some of these policies would not cover bullies from other districts or other states. Furthermore, adults who “harass” or “cyberbully” minors would not be covered in most instances. In addition, some courts have concluded that a

school district may not punish a student for out-of-school speech. See, for example, *Killion v. Franklin Regional School Dist.*, 136 F. Supp.2d 446 (W.D.Pa. 2001)(holding that school could not punish student for list disparaging the athletic director); *Flaherty v. Keystone Oaks School Dist.*, 247 F. Supp.2d 693 (W.D.Pa. 2003)(holding that the school could not punish a student for “trash talk” about a volleyball game); *Latour v. Riverside Beaver School Dist.*, No. 05-1076, 2005 WL 2106562 (W.D.Pa. August 24, 2005)(enjoining school from punishing a student for rap song lyrics).

⁷⁴ 18 U.S.C. §1030(a)(2)(C) and (c)(2)(B)(2). For example, a Missouri woman was charged with violating the federal Computer Fraud and Abuse Act for her alleged role in a MySpace hoax against a minor. The act makes it a felony punishable by up to five years of imprisonment if one “intentionally accesses a computer without authorization ..., and thereby obtains ... information from any protected computer⁷⁴ if the conduct involved an interstate ... communication” and “the offense was committed in furtherance of any ... tortious act [in this case intentional infliction of emotional distress] in violation of the ... laws ... of any State.” Prosecutors alleged that the defendant violated MySpace’s terms of use by using a fictitious name, thereby giving her no authority to access MySpace. However, the judge granted the defendant’s motion for a judgment of acquittal. In granting the defendant’s motion, the judge found that the absence of “minimal guidelines to govern law enforcement” as well as notice deficiencies made a misdemeanor violation of the CFAA based upon a “conscious violation of a website’s terms of service” void for vagueness. *United States v. Drew*, 259 F.R.O. 449 (C.D.Cal. 2009).

⁷⁵ 44 Liquormart, Inc. v. Rhode Island, 517 U.S. 484, 489 (1996); *Gitlow v. New York*, 268 U.S. 652, 666 (1925).

Chapter 103

WHITE HOUSE CONFERENCE ON BULLYING PREVENTION*

The White House

PREFACE

This chapter contains research findings, briefing materials and associated references on various aspects of bullying, prepared for the White House 2011 Conference on Bullying Prevention.

RISK FACTORS FOR AND OUTCOMES OF BULLYING AND VICTIMIZATION

Susan M. Swearer

University of Nebraska - Lincoln

No individual exists in isolation. We are all products of the interaction between our biology and our environment. The “father of social psychology,” Kurt Lewin, wrote that behavior is a function of the interaction between the individual and his or her environment (Lewin, 1936). This prophetic formula holds true for our understanding of bullying behavior. Individuals exist within multiple environments: home, school, neighborhood, church, community, and society. Within the interaction between individuals and these environments are risk factors for bullying and victimization.

In this paper research on risk factors for bullying and victimization across multiple contexts-- individual, peer, school, family, community, and society will be synthesized. It is important to keep in mind that these factors do not exist in isolation.

* These conference materials were released in 2011; Conference materials (this paper) taken from the following web site: http://www.stopbullying.gov/references/white_house_conference/index.html.

There is no, one single causal factor for bullying. In fact, it is the interaction between these multiple contexts defined as the social-ecology in which bullying and victimization unfold (Espelage & Swearer, 2004, 2011; Swearer & Doll, 2001; Swearer et al., 2006; Swearer et al., in press). Outcomes of bullying will be reviewed, with the call to address bullying as a social-ecological problem that requires prevention and intervention efforts to target the interaction between individuals and their multiple environments in order to be effective.

Prevalence of Bullying and Victimization

Given the vast methodological variation in studying bullying and victimization and the fact that bullying is a phenomenon that is idiosyncratic to individual schools and communities, determining accurate prevalence rates is spurious at best.

To date, there is no longitudinal, nationally representative assessment of bullying and victimization in the United States. However, one study analyzed prevalence rates for bullying and victimization across 22 countries and found that in the U.S. prevalence rates were 22.1% for male bully perpetrators; 15.1% for female bully perpetrators; 23.7% for male victims; 18.8% for female victims; 10.6% for male bully-victims; and 4.9% for female bully-victims (Cook, Williams, Guerra, & Kim, 2010).

However, until a nationally representative, longitudinal study on bullying and victimization is conducted, prevalence rates will reflect differences in sample characteristics and methodology.

Individual Risk Factors

Gender

While both girls and boys are involved in bullying perpetration and victimization, research has found that boys are involved in bullying at greater rates than girls (Cook, Williams, Guerra, Kim, & Sadek, 2010).

Grade Level

Bullying has generally been shown to be most prevalent in middle school (Nansel et al., 2001); however, research has suggested that bullying peaks during school transition (i.e., between elementary and middle school and between middle and high school) as youth are negotiating new peer groups and use bullying as a means to achieve social dominance (Pellegrini et al., 2011).

Ethnicity

Involvement in bullying is a cross-cultural phenomenon (Jimerson, Swearer, & Espelage, 2010) and transcends ethnicity. However, research has shown that students who are in the ethnic minority in a school are more likely to be bullied than students who are in the ethnic majority (Graham, 2006).

Religious Orientation

Surprisingly, while the media has reported on the connection between bullying and religious orientation (i.e., Muslims in the United States), a paucity of research on this risk factor for bullying has been conducted. In a study of 243 Hindu, Muslim, and Pakistani children in the U.K., 57% of boys and 43% of girls reported being bullied because of religious or cultural differences (Eslea & Mukhtar, 2000). Indeed, most students report being bullied because they are different from the normative group (Swearer & Cary, 2003).

Socioeconomic Status

Greater disparities between socioeconomic status within a country were associated with higher levels of victimization (Due et al., 2009). Other research has found that low income status was a risk factor for aggression in male and female students (Harachi et al., 2005). However, it is likely that the relationship between socioeconomic status and being bullied is contextually-driven and varies across communities.

Poor Social Skills

Bullying has been called a “social relationship problem” (Pepler, Jiang, Craig, & Connolly, 2008). Indeed, victims, bully-victims, and some bullies display deficits in social skills (Cook et al., 2010).

Superior Social Skills

However, among a subset of bully perpetrators there are students who are perceived as popular and cool (Rodkin, Farmer, Pearl, & VanAcker, 2006). For these youth, their popularity status affords them high social standing which contributes to their ability to bully and manipulate others.

Low Academic Achievement

The relationship between bullying and academic achievement is complicated. Some research has demonstrated that victims and bully victims do poorly in school (Glew, Fan, Katon, Rivara, & Kernic, 2005), while other research has found that the connection between being bullied and low academic achievement is more robust when there is low parental support and school disengagement (Beran, 2008).

Sexual Orientation

Recent media reports have drawn attention to youth who have been bullied due to their sexual orientation. Research conducted with 7,261 students (ages 13 to 21) in 2009 found that 84.6% of LGBT students reported being verbally harassed, 40.1% reported being physically harassed and 18.8% reported being physically assaulted at school in the past year because of their sexual orientation (GLSEN, 2009).

Disability Status

The research on bullying toward and by students with disabilities has yielded mixed results. Some research has found that students on the autism spectrum are more likely to be victimized than their non-disabled peers (Little, 2002). Other research has found that students with behavior disorders are more likely to perpetrate bullying, but the bullying behavior may be retaliatory, in response to being bullied (Rose, 2011).

Externalizing Behavior

One of the DSMIV-TR criteria for conduct disorder is “often bullies, threatens, or intimidates others.” Bullying is an aggressive behavior and studies have consistently found an association between conduct problems and bullying (Cook et al., 2010). Youth who are bully-victims have reported the highest levels of conduct-disordered behavior (Kokkinos & Panayiotou, 2004).

Internalizing Symptoms

Research has found that bully-victims, victims, and bullies all experience depressive disorders. In one study, 18% of bully-victims, 13% of bullies, and 10% of victims experienced depression (Kumpulainen, Rasanen, & Puura, 2001), which is higher than the estimated 8.3% of adolescents who are diagnosed with a depressive disorder (NIMH, 2011). Other research has supported the finding that bully-victims are at the greatest risk for experiencing comorbid internalizing and externalizing problems (Cook et al., 2010). In a recent study depression and suicidality were predictors of both bullying and victimization (Swearer et al., in press).

Peer Group Risk Factors***Homophily***

This term is captured by the proverb, “birds of a feather flock together” and the homophily hypothesis has been shown to explain how bullying is a peer group phenomenon (Espelage, Holt, & Henkel, 2003).

Peer Norms

When members in a peer group are involved in bullying, the other members tend to take part. Additionally, students who are involved in bully perpetration tended to come from larger peer groups (Salmivalli, Huttunen, & Lagerspetz, 1997).

Delinquency

Negative peer influence was found to predict involvement in bullying and victimization (Cook et al., 2010). In a recent study, the strongest predictor of both bullying and victimization was delinquency (measured as engaging in vandalism, being a member of a gang, and carrying a weapon onto school property) (Swearer et al., in press).

Alcohol/Drug Use

The relationship between alcohol/drug use and bullying is well-documented. In a study of middle through high school students, researchers found that aggressive victims and aggressive non-victims were more likely than their non-aggressive counterparts to use drugs and alcohol (Brockenbrough, Cornell, & Loper, 2002) and a study of 43, 093 U.S. adults found that bullying was significantly correlated with lifetime alcohol and drug use (Vaughn, Bender, DeLisi, Beaver, Perron, & Howard, 2010). Thus, involvement in bullying is related to concurrent alcohol/drug use as well as future alcohol/drug use.

School Risk Factors

School Climate

The adults in our nation's schools play a major role in creating a positive or negative school climate. When the school climate is not supportive and unhealthy, then bullying and concomitant problems proliferate (Kasen, Johnson, Chen, Crawford, & Cohen, 2011). Schools where high levels of bullying exist are schools that have a negative and punitive school climate.

Teacher Attitudes

When adults in the school system ignore bullying or feel that bullying is just “kids being kids,” then higher levels of bullying will exist (Holt, Keyes, & Koenig, 2011).

Classroom Characteristics

Schools are comprised of classrooms and it stands to reason that healthy classroom environments will have less bullying and victimization. There are four classroom characteristics that have been found to be associated with greater levels of bullying and victimization: (1) negative peer friendships, (2) poor teacher-student relationships, (3) lack of self-control, and (4) poor problem-solving among students (Doll, Song, Champion, & Jones, 2011).

Academic Engagement

When students are challenged and motivated to do well in school, engagement in bullying and victimization is lower. Students involved in bullying and victimization are less academically engaged (Nansel, Haynie, & Simons-Morton, 2003).

School Belonging

Elementary students who bullied others reported lower rates of school belonging than students who were victimized or not involved in bullying (Ma et al., 2009). Data from 16,917 middle and high school students showed that feelings of school belonging were associated with less bullying and victimization (Swearer et al., in press).

Family Risk Factors

Parental Characteristics

In a synthesis of research on family characteristics of bullies, bully-victims, and victims, psychologist Renae Duncan (2011) found that bullies typically come from families with low cohesion, little warmth, absent fathers, high power needs, permit aggressive behavior, physical abuse, poor family functioning, and authoritarian parenting. Bully-victims come from families with physical abuse, domestic violence, hostile mothers, powerless mothers, uninvolved parents, neglect, low warmth, inconsistent discipline, and negative environment. Male victims had mothers who were overprotective, controlling, restrictive, coddling, overinvolved, and warm while their fathers were distant, critical, absent, uncaring, neglectful, and controlling. Female victims had mothers who were hostile, rejecting, withdrawing love, threatening, and controlling, while their fathers were uncaring and controlling.

Family Discord

Being in a family where parents fight and use drugs and alcohol and who are physically or sexually abusive predicted both bully perpetration and victimization (Swearer et al., in press). Youth who bully others consistently report family conflict and poor parental monitoring (Cook et al., 2010).

Community Risk Factors***Neighborhoods***

Characteristics of neighborhoods have a significant effect on bullying behavior (Cook et al., 2010). Neighborhoods that are unsafe, violent, and disorganized are breeding grounds for bullying. Living in a safe, connected neighborhood predicted less bullying and victimization (Swearer et al., in press).

Societal Risk Factors***Media***

Decades of research have examined the question of whether or not exposure to violent video games, television, and film are associated with greater levels of aggression. In fact, meta-analyses of these studies clearly support the fact that media violence is correlated with aggressive and antisocial behavior (Gentile, 2003). A recent study examining the dosage effects of playing mature video games predicted greater risk for bully perpetration among middle school students (Olson, Kutner, Baer, Beresin, Warner, & Nicholi, 2009).

Intolerance

Discrimination and prejudice have been documented since Biblical times. Prejudices such as homophobia, sexism, classism, racism, set fertile ground for bullying and victimization.

Outcomes of Bullying and Victimization

The aforementioned social-ecological risk factors for bullying and victimization clearly paint a bleak picture for the outcomes of bullying and victimization. The bottom line is that without effective intervention, the consequences of bullying and victimization are dire for individuals, peer groups, schools, families, communities, and society at large.

Biological

Studies of early social deprivation have demonstrated that the social environment alters brain functioning (Chugani et al., 2001). This and other research have been extended to our understanding of how bullying experiences can alter brain chemistry and functioning. The stress of being bullied has been hypothesized to depress immune functioning and research has found that cortisol moderated the link between being bullied and physical health (Vaillancourt et al., 2010). As neuroscientists have long argued, it is impossible to separate the brain from behavior.

Educational

According to the National Association of School Psychologists (http://www2.ed.gov/admins/lead/safety/training/bullying/bullying_pg14.html), over 160,000 students miss school each day due to fears of being bullied. It stands to reason that bullying detracts from academic achievement and research supports this negative outcome (Glew et al., 2005).

Psychological

The psychological outcomes of bullying are well-established in the research literature. Individuals involved in bullying and victimization have higher levels of depression, anxiety, and externalizing behavior (Cook et al., 2010; Menesini, Modena, & Tani, 2009; Espelage & Swearer, 2011).

Conclusion

Two decades of basic research have illuminated the risk factors and negative outcomes of bullying and victimization. The picture for our nation's youth is bleak. Researchers and educators have argued that research across the social ecology must inform bullying prevention and intervention practices if we ever hope to significantly reduce bullying in our nation's schools (Swearer, Espelage, Vaillancourt, & Hymel, 2010). Bullying and victimization are social-ecological phenomena that require comprehensive, data-based prevention and intervention efforts.

FINDINGS FROM THE NATIONAL EDUCATION ASSOCIATION'S NATIONWIDE STUDY OF BULLYING: TEACHERS' AND EDUCATION SUPPORT PROFESSIONALS' PERSPECTIVES

Michaela Gulemetova and Darrel Drury

National Education Association

Catherine P. Bradshaw

Johns Hopkins University

Executive Summary

This research brief reports the results of a National Education Association (NEA) survey of teachers and education support professionals (ESPs)ⁱ that addresses the problem of bullying in America's public schools. The study finds that bullying is not only pervasive in the nation's schools but also widely perceived by school staff to be a serious problem, particularly in middle schools and in schools located in urban areas. The vast majority of school staff reported that their district had implemented a bullying prevention policy. However, ESPs were significantly less likely than teachers to have received formal training or to have been involved in bullying prevention activities, such as committees, teams, or prevention programs. In light of these disparities, it is not surprising that, although ESPs were nearly as likely as their teacher counterparts to indicate that it was "their job" to intervene, they expressed significantly less comfort in taking action in a wide range of bullying situations. The fact that ESPs report high levels of connectedness to their respective school communities, combined with evidence that such subjective feelings tend to be associated with a greater willingness to intervene, suggests that ESPs represent an invaluable resource and should be included in the design and implementation of future prevention programs. The very presence of ESPs in areas throughout the school where bullying regularly occurs—on playgrounds, school busses, cafeterias and hallways—further substantiates this conclusion.

Introduction

Bullying continues to be a major concern among students and staff in the nation's public schools and, most recently, has been the focus of widespread public attention as a result of several high-profile incidents. The National Education Association (NEA) has had a long history of involvement in bullying prevention efforts.ⁱⁱ With 3.2 million members, representing both teaching and non-teaching staff, the NEA is in a unique position to address bullying from a whole-school perspective—through its existing programs and through research aimed at developing a better understanding of the role that a united education workforce can play in dealing with this critical issue. Toward that end, in April 2010 the NEA drew upon its membership to implement a national survey examining school staff members' perceptions of bullying among students. The overall goal of the study was to identify strengths as well as areas

of need related to bullying prevention to inform future prevention efforts, both within the NEA and in collaboration with other agencies.

The NEA study is the first of its kind to examine both teachers and education support professionals (ESPs)—including bus drivers, cafeteria workers, custodians, and other support staff—in a nationwide study of bullying.ⁱⁱⁱ Much of what is currently known about bullying prevention is limited to how teachers and students perceive bullying and the actions they take in response to such behavior. However, bullying incidents regularly occur outside of the classroom and, therefore, may be beyond the awareness of teachers. Inasmuch as ESPs represent about one-third of school staff and typically work in non-classroom settings where bullying often takes place, it is essential that we develop a better understanding of the attitudes, behaviors, and concerns of ESPs pertaining to this issue and apply that knowledge to the design and implementation of more effective prevention programs. This brief summarizes findings from this unique study in an effort to promote collaboration in bullying prevention in the nation's public schools.^{iv}

Key Findings from the NEA Bullying Study

School staff perceived bullying to be a problem in their school; they witnessed bullying frequently and students reported it to them in large numbers. Over 40 percent of respondents indicated that bullying was a moderate or major problem in their school, with 62 percent indicating that they witnessed two or more incidents of bullying in the last month, while 41 percent witnessed bullying once a week or more. Although more teachers (45%) than ESPs (35%) indicated that a student reported bullying to them within the past month, all staff members equally indicated that parents had reported bullying to them (16%). Across school levels and communities, staff working in middle schools and in urban areas were more likely to report that they had frequently witnessed bullying (66% and 65%, respectively) and were more likely to perceive it as a serious problem (59% and 54%, respectively).

There was a discrepancy between the existence of school district bullying policies and staff members' self-reported training on these policies. Although the vast majority of school employees (93%) reported that their district had implemented a bullying prevention policy, only about half of all staff had received training related to the policy. ESPs were significantly less likely to report that they had received training on their district's policy than teachers (45% and 54%, respectively). Staff in urban schools, where the rates of staff-reported bullying were highest, were less likely to report the existence of a district-wide policy (88%) and less likely to have received training on the policy (51%).

Bullying takes many forms, with school staff reporting that verbal (59%), social/relational (50%), and physical (39%) forms were of greater concern in their school than cyber-bullying (17%). All staff reported that bullying based on a student's weight (23%), gender (20%), perceived sexual orientation (18%), and disability (12%) were of concern in their school. Both teachers and ESPs reported a need for additional training in intervening with different forms of bullying, but ESPs expressed greater need than teachers in dealing with physical, verbal, and relational bullying, as well as the more recent phenomenon, "sexting." All school staff reported the greatest need for training on cyber-bullying and bullying related to sexual orientation and gender issues; they also reported being the least comfortable intervening in these types of

bullying situations. In addition, ESPs reported that they were less comfortable intervening in physical, verbal, and relational forms of bullying.

Although school staff reported being very willing to intervene in bullying situations, slightly over half of the survey respondents indicated that there were few formal bullying prevention activities present in their schools, and less than 40 percent were directly involved in these activities. Across all school levels and communities, most school employees felt that it was ‘their job’ to intervene when they witnessed bullying incidents, though teachers and ESPs differed in their responses (99% of teachers and 91% of ESPs agreed). Overall, however, only 58 percent of staff reported that their school had implemented formal bullying prevention efforts such as school teams, committees, or prevention programs. Even fewer reported the presence of such prevention activities in schools located in urban areas (47%) and in high schools (51%). Teachers were significantly more likely than ESPs to be directly involved in bullying prevention activities (42% and 27%, respectively). The lowest level of staff involvement in bullying prevention activities was in high schools (24%).

An important predictor of staff members’ willingness to intervene in bullying situations was their subjective sense of connectedness to the school, defined as “the belief held by adults in the school that they are cared about as individuals and professionals involved in the learning process.” Specifically, school staff members’ perceptions of their relationships with colleagues and school administrators, their perceptions of safety, and their overall sense of belonging within the school community were associated with a greater likelihood of intervening in bullying situations. Moreover, staff members’ belief that other school staff were likely to intervene in bullying incidents was associated with a greater likelihood that they themselves would intervene. ESPs reported high levels of personal connectedness, connectedness with the administration, and overall connectedness to the school community. This may, in part, be attributable to the fact that ESPs tend to reside within the neighborhoods surrounding the schools in which they work. Feelings of connectedness also varied across school levels and urbanicity, with staff in high schools and in schools located in urban communities reporting the lowest levels of connectedness.

Conclusion and Implications

Given the high rates of bullying in schools, it is not surprising that teachers and other school staff express great concern about this issue. Although bullying policies appear to exist in many districts, there seems to be a lack of sufficient instruction on the implementation of those policies. School staff, especially ESPs, reported a great need for additional training to help them confidently intervene in bullying situations. With less than 60% of members reporting that their school had formal bullying prevention efforts in place, there should be a greater emphasis on the implementation of evidence-based bullying prevention programs.

There is ample evidence that students who experience bullying suffer a range of adverse academic and health effects (Swearer, Espelage, Vaillancourt, & Hymel, 2010). Large numbers of students are seeking help from teachers, as well as from ESPs. The findings from the current study indicate that ESPs tend to live in the community served by their schools and express high levels of connectedness to the school community. ESPs’ strong connections to both the school and students make them a natural source of support for students in need. Moreover, given the fact that a significant portion of bullying occurs in areas such as the cafeteria, playground, and

school busses, intervention programs should more actively include ESPs and other school staff who have the opportunity to supervise these areas. ESPs appear to represent an untapped resource in schools, many of whom appear eager to be involved in preventative interventions programs.

This study suggests that school staff connectedness may serve as an important lever for bullying prevention efforts, as the more connected school employees feel to their school community, the more likely they may be to become involved in bullying prevention efforts. A recent study of School-Wide Positive Behavior Supports found that high fidelity implementation of the model was associated with significant improvements in staff members' connectedness to others within the school (Bradshaw, Koth, Thornton, & Leaf, 2009); thus Positive Behavior Supports may also have an impact on staff members willingness to intervene and participate in prevention efforts, as well as on students' bullying behavior (Waasdorp, Bradshaw, & Leaf, 2011).

Taken together, the findings of the NEA Bullying Study provide great insight into staff members' perceptions of bullying, including the unique perspectives of different groups of ESPs (e.g., bus drivers, cafeteria workers, security officers), who are often overlooked in the literature. To our knowledge, this investigation presents findings from the only large-scale nationwide survey fielded to examine different staff members' perspectives on bullying and prevention efforts. As such, this study helps to elucidate the specific needs of various groups of adults who work in schools across the country. These findings may also inform the creation of professional development and training materials tailored for different school staff and for those working with special populations of students across different grade levels and community contexts.

OVERVIEW OF CYBERBULLYING

Sameer Hinduja, Ph.D.

Florida Atlantic University

Justin W. Patchin, Ph.D.

University of Wisconsin-Eau Claire

Cyberbullying Research Center

www.cyberbullying.us

Kids have been bullying each other for generations. The latest generation, however, has been able to utilize technology to expand their reach and the extent of their harm.

This phenomenon is being called *cyberbullying*, defined as: “*willful and repeated harm inflicted through the use of computers, cell phones, and other electronic devices*” (Hinduja & Patchin, 2009:5). Basically, we are referring to incidents where adolescents use technology, usually computers or cell phones, to harass, threaten, humiliate, or otherwise hassle their peers.

Where Does Cyberbullying Commonly Occur?

Cyberbullying occurs across a variety of venues and mediums in cyberspace, and it shouldn’t come as a surprise that it occurs most often where teenagers congregate. Initially, many teens hung out in chat rooms, and as a result that is where most harassment took place. In recent years, most youth have been drawn to social networking websites (such as Facebook) and video-sharing websites (such as YouTube). This trend has led to increased reports of cyberbullying occurring in those environments (Burgess-Proctor, Patchin, & Hinduja, 2009; Hinduja & Patchin, 2008b; R. M. Kowalski & Limber, 2007; Lenhart, 2007; Li, 2007a; Patchin & Hinduja, 2006). Instant messaging on the Internet or text messaging via a cell phone also

appear to be common ways in which youth are harassing others. Moreover, since most cell phones attractive to youth are “smart” phones (e.g., iPhones, Blackberries, Droids), they often have full computing, recording, and Internet capabilities on a device that is always with them. Adolescents have sometimes taken pictures in a bedroom, a bathroom, or another location where privacy is expected, and posted or distributed them online. More recently, some have recorded unauthorized videos of other teens and uploaded them for the world to see, rate, tag, and discuss. We are also seeing it happen with portable gaming devices, in 3-D virtual worlds and on social gaming sites, and in newer interactive sites such as Formspring and ChatRoulette.

How Much Cyberbullying Is out There?

Estimates of the number of youth who experience cyberbullying vary widely (ranging from 5-40% or more), depending on the age of the group studied, how cyberbullying is formally defined, and the research methodology (Hinduja & Patchin, 2007, 2009, 2010c; R. M. Kowalski & Limber, 2007; Li, 2007b; Williams & Guerra, 2007; Ybarra & Mitchell, 2004). In our work, we inform students that cyberbullying is when someone “repeatedly makes fun of another person online or repeatedly picks on another person through email or text message or when someone posts something online about another person that they don’t like.” Using this definition, about 20% of the over 4,400 randomly-selected 11-18 year-old students we surveyed in 2010 indicated they had been a victim at some point in their life. About this same number admitted to cyberbullying others during their lifetime (Hinduja & Patchin, forthcoming). Finally, about 10% of teens in this recent study said they had both been a victim and an offender.

What Are Some of the Negative Effects That Cyberbullying Can Have on a Person?

There are many detrimental outcomes associated with cyberbullying that reach into the real world. First, many targets of cyberbullying report feeling depressed, sad, angry, and frustrated (Hinduja & Patchin, 2007, 2008a, 2009; Kowalski, Limber, Scheck, Redfearn, Allen, Calloway, & Farris, 2005; Kowalski & Limber, 2007; Li, 2007a, 2007b; Patchin & Hinduja, 2006; Williams & Guerra, 2007; Ybarra & Mitchell, 2004), and these emotions have been correlated with delinquency and interpersonal violence among youth (Berson, Berson, & Ferron, 2002; Cowie & Berdondini, 2002; Ybarra & Mitchell, 2007). As one teenager stated: “It makes me hurt both physically and mentally. It scares me and takes away all my confidence. It makes me feel sick and worthless.” Victims who experience cyberbullying also reveal that they were afraid or embarrassed to go to school.

In addition, research has revealed a link between cyberbullying and low self-esteem, family problems, academic problems, school violence, and delinquent behavior (Hinduja & Patchin, 2007, 2008a, 2009; Patchin & Hinduja, 2010; Ybarra, Diener-West, & Leaf, 2007; Ybarra & Mitchell, 2004). Finally, cyberbullied youth also report having suicidal thoughts, and there have been a number of examples in the United States where youth who were victimized ended up taking their own lives (Hinduja & Patchin, 2010a).

Lifetime Cyberbullying Victimization Rates

Seven Different Studies 2004-2010

Sameer Hinduja and Justin W. Patchin

Cyberbullying Research Center - www.cyberbullying.us

How Is Cyberbullying Different from Traditional Bullying?

While often similar in terms of targeting peers with hurtful words or threats, bullying and cyberbullying have many differences that can make the latter even more devastating.

Lifetime Cyberbullying Offending Rates

Seven Different Studies 2004-2010

Sameer Hinduja and Justin W. Patchin

Cyberbullying Research Center - www.cyberbullying.us

First, victims sometimes do not know who the bully is, or why they are being targeted. The cyberbully can cloak his or her identity behind a computer or cell phone using anonymous email addresses or pseudonymous screen names (Hinduja & Patchin, 2008a). Second, the hurtful actions of a cyberbully are viral; that is, a large number of people (at school, in the neighborhood, in the city, in the world!) can be involved in a cyber-attack on a victim, or at least find out about the incident with a few keystrokes or clicks of the mouse. The perception, then, is that absolutely everyone is in on the joke.

Third, it is often easier to be cruel using technology because cyberbullying can be done from a physically distant location, and the bully doesn't have to see the immediate response by the target (Willard, 2007). In fact, some teens simply might not recognize the serious harm they are causing because they are sheltered from the victim's response. Finally, while parents and teachers are doing a better job supervising youth at school and at home, many adults don't have the technological know-how to keep track of what teens are up to online. As a result, a victim's experience may be missed and a bully's actions may be left unchecked. Even if bullies are identified, many adults find themselves unprepared to adequately respond.

Why Is Cyberbullying Becoming a Major Issue?

Cyberbullying is a growing problem because increasing numbers of teens are using and have completely embraced interactions via computers and cell phones. Two-thirds of youth go online every day for school work, to keep in touch with their friends, to play games, to learn about celebrities, to share their digital creations, or for many other reasons (Lenhart, Purcell, Smith, & Zickuhr, 2010). Because the online communication tools have become an important part of their lives, it is not surprising that some teens have decided to use these devices to be malicious or menacing towards others. The fact that teens are connected to technology 24/7 means they are susceptible to victimization (and able to act on mean intentions toward others) around the clock (Kowalski, Limber, & Agatston, 2007). Apart from a measure of anonymity, it is also easier to be hateful using typed words rather than spoken words face-to-face. And because some adults have been slow to respond to cyberbullying, many cyberbullies feel that there are little to no consequences for their actions.

Despite these differences, a significant body of research notes the close connection between experiences with online and offline bullying. While it is difficult to determine whether being a bully or being bullied in the real world *causes* similar experiences in cyberspace (or vice versa), a clear correlation between the two spheres of interaction exists. For example, Ybarra and Mitchell (2004) found that about half of cyberbullying victims and offenders report also experiencing traditional, offline bullying (see also Hinduja & Patchin, 2009) and we Hinduja & Patchin, 2008 found that traditional bullies were more than twice as likely to be both the victims and the perpetrators of electronic forms of bullying compared to those who do not engage in traditional bullying. Moreover, victims of offline bullying were 2.7 times as likely to also be a victim of cyberbullying compared to those who hadn't experienced offline bullying.

What Can Parents Do?

The best tack parents can take when their child is cyberbullied is to make sure they feel (and are) safe and secure, and to convey unconditional support. Parents must demonstrate to

their children through words and actions that they both desire the same end result: that the cyberbullying stop and that life does not become even more difficult. This can be accomplished by working together to arrive at a mutually-agreeable course of action, as sometimes it is appropriate (and important) to solicit the child's perspective as to what might be done to improve the situation. If necessary, parents should explain the importance of scheduling a meeting with school administrators (or a teacher they trust) to discuss the matter. Parents may also be able to contact the father or mother of the offender, and/or work with the Internet Service Provider, Cell Phone Service Provider, or Content Provider to investigate the issue or remove the offending material. The police should also be approached when physical threats are involved or a crime has possibly been committed.

Overall, parents must educate their children about appropriate online behaviors (and teens must follow these guidelines!). They should also monitor their child's activities while online – especially early in their exploration of cyberspace. This can be done informally (through active participation in your child's Internet experience, which we recommend most of all) or formally (through software). Cultivate and maintain an open, candid line of communication with your children, so that they are ready and willing to come to you whenever they experience something unpleasant or distressing when interacting via computer or cell phone. Model, teach, and reinforce positive morals and values, and instill in youth the importance of treating others with respect and dignity, whether online or off.

Parents may also utilize an "Internet Use Contract" and a "Cell Phone Use Contract" to foster a crystal-clear understanding about what is and is not appropriate with respect to the use of technology. Within these documents, both the child and the parent agree to abide by certain mutually-acceptable rules of engagement. To remind the child of this pledged commitment, it is recommended that this contract be posted in a highly visible place (e.g., next to the computer). When there are violations to this contract, immediate consequences must be given that are proportionate to the misbehavior, and that leave an impact. Teens need to learn that inappropriate online actions will not be tolerated. Victims of cyberbullying (and the bystanders who observe it) must know for sure that the adults who they tell will intervene rationally and logically, and not make the situation worse.

If a parent discovers that their child is cyberbullying others, they should first communicate how that behavior inflicts harm and causes pain in the real world as well as in cyberspace. Depending on the level of seriousness of the incident, and whether it seems that the child has realized the hurtful nature of his or her behavior, consequences should be firmly applied (and escalated if the behavior continues). If the incident was particularly severe, parents may want to consider installing tracking or filtering software, or removing technology privileges altogether for a period of time. Moving forward, it is essential that parents pay even greater attention to the Internet and cell phone activities of their child to make sure that they have internalized the lesson and are acting in responsible ways.

What Should Schools Do to Prevent Cyberbullying?

Cyberbullying that is initiated using computer on campus – such as in a school lab or on school-issued laptops, or even via personally-owned devices (cell phones, iPads, netbooks) between or during classes – can obviously affect the mission, value system, and goals of a school. However, even if cyberbullying originates off-campus from a student's home computer

or phone, it can lead to the same problematic outcomes on campus. This is because the social and relational fallout frequently carries over into the school environment since it mostly involves conflict between students who know each other, rather than involving strangers (Hinduja & Patchin, 2007, 2008a, 2009, 2010a; McQuade & Sampat, 2008; Wolak, Mitchell, & Finkelhor, 2007; Ybarra, et al., 2007; Ybarra & Mitchell, 2004). As such, the school is necessarily implicated in a large number of these cases, which not only tends to compromise the safety and well-being of youth, but also undermines the positive school climate that teachers, staff, and administrators have worked to create.

The most important preventive step is to educate the school community about responsible Internet interactions. Students need to know that all forms of bullying are wrong and that those who engage in harassing or threatening behaviors will be subject to discipline. It is therefore important to discuss issues related to the appropriate use of online communications technology in various areas of the general curriculum – and not just in technology-related classes. To be sure, these messages should be reinforced in classes that regularly utilize technology. Signage also should be posted in the computer lab or at each computer workstation to remind students of the rules of acceptable use. In general, it is crucial to establish and maintain a school climate of respect and integrity where violations result in informal or formal sanction (Davis & Davis, 2007b).

Furthermore, school district personnel should review their harassment and bullying policies to see if they allow for the discipline of students who engage in cyberbullying. If their policy covers it, cyberbullying incidents that occur at school - or that originate off campus but ultimately result in a substantial disruption of the learning environment - are well within a school's legal authority to intervene. The school then needs to make it clear to students, parents, and all staff that these behaviors are unacceptable and will be subject to discipline. In some cases, simply discussing the incident with the offender's parents will result in the behavior stopping.

What Should Schools Do to Respond to Cyberbullying?

Students should already know that cyberbullying is unacceptable and that the behavior will result in discipline. Utilize school liaison officers or other members of law enforcement to thoroughly investigate incidents, as needed, if the behaviors cross a certain threshold of severity. Once the offending party has been identified, develop a response that is commensurate with the harm done and the disruption that occurred.

School administrators should also work with parents to convey to the student that cyberbullying behaviors are taken seriously and are not trivialized. Moreover, schools should come up with creative response strategies, particularly for relatively minor forms of harassment that do not result in significant harm. For example, students may be required to create anti-cyberbullying posters to be displayed throughout the school. Older students might be required to give a brief presentation to younger students about the importance of using technology in ethically-sound ways. The point here, again, is to condemn the behavior while sending a message to the rest of the school community that bullying in any form is wrong and will not be tolerated.

Even though the vast majority of these incidents can be handled informally (calling parents, counseling the bully and target, expressing condemnation of the behavior), there may be

occasions where formal response from the school is warranted. This is particularly the case in incidents involving serious threats toward another student, if the target no longer feels comfortable coming to school, or if cyberbullying behaviors continue after informal attempts to stop it have failed. In these cases, detention, suspension, changes of placement, or even expulsion may be necessary. If these extreme measures are required, it is important that educators are able to clearly demonstrate the link to school and present evidence that supports their action.

How Is Cyberbullying and School Climate Related?

The benefits of a positive school climate have been identified through much research over the last thirty years. It contributes to more consistent attendance, higher student achievement, and other desirable student outcomes. Though limited, the research done on school climate and traditional bullying also underscores its importance in preventing peer conflict. Existing research has consistently identified an inverse relationship between specific components of school climate and bullying among students (e.g., Gottfredson & Gottfredson, 1985; Malecki & Demaray, 2004; Rigby, 1996; Whitney & Smith, 1993).

Also, a school climate that condones bullying (Olweus, Limber, & Mihalic, 1999) within a high-conflict, disorganized school environment tends to exacerbate the problem of bullying (Kasen, Berenson, Cohen, & Johnson, 2004). Finally, youth who are introduced to and adopt normative beliefs that support peer aggression are more likely to bully others (Bentley & Li, 1995; Espelage & Swearer, 2003; Huesmann, 1997; Olweus, 1991).

One of our recent studies found that students who experienced cyberbullying (both those who were victims and those who admitted to cyberbullying others) perceived a poorer climate at their school than those who had not experienced cyberbullying. Youth were asked whether they “enjoy going to school,” “feel safe at school,” “feel that teachers at their school really try to help them succeed,” and “feel that teachers at their school care about them.” Those who admitted to cyberbullying others or who were the target of cyberbullying were less likely to agree with those statements.

Overall, it is critical for educators to develop and promote a safe and respectful school climate. A positive on-campus environment will go a long way in reducing the frequency of many problematic behaviors at school, including bullying and harassment. In this setting, teachers must demonstrate emotional support, a warm and caring atmosphere, a strong focus on academics and learning, and a fostering of healthy self-esteem. Additionally, it is crucial that the school seeks to create and promote an atmosphere where certain conduct not tolerated—by students and staff alike. In schools with healthy climates, students know what is appropriate and what is not.

One way to combat cyberbullying is to create a positive school climate. The benefits of a positive school climate have been identified through much research as improved attendance, student achievement, perceived and actual campus safety, and other desirable student outcomes, along with decreased peer-on-peer bullying. The following are ways to foster a positive climate at school:

- Constantly demonstrate emotional support, a warm and caring atmosphere, a strong focus on academics and learning, and encourage healthy self-esteem among students.

- Offer training workshops for staff to get them up to speed on the positive and negative uses of Facebook, YouTube, FormSpring, ChatRoulette, instant messaging programs, chat rooms, message boards, and cell phones.
- Hold assemblies for students that are relevant, hard-hitting, and meaningful, emphasizing that the *vast majority* of kids do the right thing with their computers and cell phones and that appropriate and wise Internet participation is the social norm. This should inspire the rest to “get on board.”
- Use peer mentoring by having older students informally teach lessons and share learning experiences with younger students to promote positive online interactions.
- Establish clear rules about the use of the Internet, computers, and other electronic devices, making sure to cover online harassment. Post eye-catching signs or posters in school computer labs, hallways, and classrooms to remind students to use technology responsibly.
- Create a formal behavioral contract specific to cyberbullying or introduce clauses within the formal “respect policy” or “honor code” that identify cyberbullying as inappropriate behavior. Do what you can to make sure this policy or honor code is viewed as sacred among students.
- Share important facts, reminders, and guidance about cyberbullying over the audio or video morning announcements on a weekly basis.
- Develop *anonymous* ways for students to report situations or incidents that may weaken the school climate (cyberbullying and other forms of harassment). Post a web form on the school’s web page, create an e-mail account where messages are forwarded to the counselor or assistant principal, or provide a cell phone number to which students can text their concerns.
- Develop a website, blog, Facebook group, or Twitter page for parents and students to further inform them about your school’s position and how you will respond to incidents. Send out news, reminders, and links to stories involving appropriate and inappropriate online communications among young adolescents to keep these issues in the forefront of their minds and reinforce them as priority issues for your school.
- Motivate students to initiate an anticyberbullying awareness or pledge campaign. Let them come up with a very cool and relevant design for their hard-hitting message, then approach local businesses and organizations to sponsor the production of T-shirts, buttons, pins, key chains, magnets, or bumper stickers to spread the word.

Cultivating a positive climate on campus will not only promote student achievement, success, and productivity, it will decrease peer harassment—online and offline.

What Can Youth Do?

Most importantly, youth should develop a relationship with an adult they trust (a parent, teacher, or someone else) so they can talk about any experiences they have online (or off) that make them upset or uncomfortable. If possible, teens should ignore minor teasing or name calling, and not respond to the bully as that might simply make the problem continue. It’s also useful to keep all evidence of cyberbullying to show an adult who can help with the situation.

If targets of cyberbullying are able to keep a log or a journal of the dates and times and instances of the online harassment, that can also help prove what was going on and who started it.

Overall, youth should go online with their parents – show them what web sites they use, and why. At the same time, they need to be responsible when interacting with others on the Internet. For instance, they shouldn't say anything to anyone online that they wouldn't say to them in person with their parents in the room. Finally, youth ought to take advantage of the privacy settings within Facebook and other websites, and the social software (instant messaging, email, and chat programs) that they use – they are there to help reduce the chances of victimization. Users can adjust the settings to restrict and monitor who can contact them and who can read their online content.

What Can Bystanders Do?

Bystanders also have a very critical role to play. Those who witness cyberbullying generally do not want to get involved because of the hassle and problems they fear it might bring upon them, yet they often recognize that what they are seeing is not right and should stop (Davis & Davis, 2007a). However, by doing *nothing*, bystanders are doing *something*. We have a responsibility to look out for the best interests of each other. Bystanders can make a huge difference in improving the situation for cyberbullying victims, who often feel helpless and hopeless and need someone to come to the rescue. Bystanders should note what they see and when. They should also stand up for the victim, and tell an adult they trust who can really step in and improve the situation (Patchin & Hinduja, forthcoming). Finally, they should never encourage or indirectly contribute to the behavior – by forwarding hurtful messages, laughing at inappropriate jokes or content, condoning the act just to “fit in,” or otherwise silently allowing it to continue (Hinduja & Patchin, 2009).

What Can Law Enforcement Do?

Law enforcement officers also have a role in preventing and responding to cyberbullying. To begin, they need to be aware of ever-evolving state and local laws concerning online behaviors, and equip themselves with the skills and knowledge to intervene as necessary (Patchin & Hinduja, forthcoming). In a recent survey of school resource officers, we found that almost one-quarter did not know if their state had a cyberbullying law. This is surprising since their most visible responsibility involves responding to actions which are in violation of law (e.g., harassment, threats, stalking). Even if the behavior doesn't immediately appear to rise to the level of a crime, officers should use their discretion to handle the situation in a way that is appropriate for the circumstances. For example, a simple discussion of the legal issues involved in cyberbullying may be enough to deter some youth from future misbehavior. Officers might also talk to parents about their child's conduct and express to them the seriousness of online harassment.

Relatedly, officers can play an essential role in preventing cyberbullying from occurring or getting out of hand in the first place. They can speak to students in classrooms about cyberbullying and online safety issues more broadly in an attempt to discourage them from engaging in risky or unacceptable actions and interactions. They might also speak to parents

about local and state laws, so that they are informed and can properly respond if their child is involved in an incident.

BULLYING AND CHILDREN'S PEER RELATIONSHIPS

Philip C. Rodkin

University of Illinois at Urbana-Champaign

On first thought, the words *bully* and *peer* hardly belong in the same title; for all intents and purposes the two words are opposites. A peer is an equal, of the same social standing as oneself (Hartup, 1983). Bullying lacks the elements of equality and free choice. What distinguishes bullying from other forms of childhood aggression, whether a hard-fought basketball game or rough-and-tumble play, is *unequal, coercive power* (Olweus, 1993; Vaillancourt, McDougall, Hymel, & Sunderani, 2010). It's this sense of inequality, abuse, unfairness, and of a peer culture valuing all the wrong things that makes the problem of bullying fundamentally incompatible with the American character. Bullying violates our democratic spirit that all youth should be free to learn, in peace and safety, making the most of their talents and goals.

What kind of power does a bully really have? Children and youth (and some adults) use bullying to acquire resources and—here is where peers come into the picture—to demonstrate to an audience that they can dominate (Pellegrini, Long, Solberg, Roseth, DuPuis, Bohn, & Hickey, 2010; Salmivalli, Kärnä, & Poskiparta, 2010). The success of bullies in attaining resources and recognition—indeed, the very extent to which children turn to bullying-- depends on factors that include the characteristics of the bully, the relationship existing between bullies and whom they target for harassment, and the reactions of classmates who witness bullying. Do schoolmates embarrass the harassed and stroke the bully's ego, do they ignore the bullying in front of their eyes, or does somebody intervene to support the victim and help stop the bullying? Of course, peer culture in elementary, middle, and high school exists not in some *Lord of the Flies* lawlessness, but rather under the presumably watchful eyes of responsible adults: teachers, principals, bus drivers, school staff, and of course parents. The importance of how peers and adults act in response to—or even better, in anticipation of bullying, can't be overestimated.

Two Social Worlds of Bullying

In a recent article, Tom Farmer and his colleagues report on the “two social worlds” of bullying (Farmer, Petrin, Robertson, Fraser, Hall, Day, & Dadisman, 2010). These social worlds are *marginalization* on the one hand, and *connection* on the other. To quote Farmer and colleagues, socially marginalized bullies “may be fighting against a social system that keeps them on the periphery” while socially integrated bullies “may use aggression to control” others (p. 386).

With respect to rejection and marginalization, many bullies seem to continuously come into conflict with others, to run against the world. These children, mostly boys, tend to be characterized by a clear pattern of deficits in broad domains of developmental functioning. They’re consistently identified as being at-risk, even from bullying and harassment by others (what Olweus (1993) terms “bully-victims”). Their aggression is impulsive and overly reactive to real or perceived slights. Cook, Williams, Guerra, Kim, and Sadek (2010, p. 76) write that this type of bully: “has comorbid externalizing and internalizing problems, holds significantly negative attitudes and beliefs about himself or herself and others, is low in social competence, does not have adequate social problem-solving skills, performs poorly academically, and is not only rejected and isolated by peers but also negatively influenced by the peers with whom he or she interacts.” Farmer and colleagues report that marginalized, unpopular bullies, whether girls or boys, are often shunted into peer groups with other bullies, and sometimes even with the children they harass. Marginalized bullies have a host of problems of which bullying behavior is but one manifestation. Their bullying might stem from an inability to control their impulsive actions, or from a desire to gain status that generally eludes them.

Then there are bullies whose social worlds are networked and integrated—these children don’t lack for peer social support. Socially integrated bullies are more evenly split between boys and girls. They have a variety of friends, some bullies but others not, and strengths that are easy to recognize, like social skills, athleticism, or attractiveness. Socially connected bullies tend to be proactive and goal-directed in their aggression. They have lots of experience with peers, perhaps as far back as the day care years (Rodkin & Roisman, 2010). Some bullies incorporate prosocial strategies into their behavioral repertoire, for example reconciling with their targets after conflict, or becoming less aggressive once a clear dominance relationship has been established (Pellegrini et al., 2010). Socially connected bullies are both underrecognized as seriously aggressive, and popularized in the media as in, for instance, *Mean Girls*. Vaillancourt and colleagues (2010, p. 218) go so far as to call these socially connected bullies “Machiavellian”: “popular, socially skilled and competent... [with] high self-esteem.. low on psychopathology... [and] many assets” (see also Hawley, 2003). This portrait of mental health may be overdrawn, as Cook and colleagues (2010) and Rodkin and Roisman (2010) find substantial deficits even for more popular bullies, but there is no doubt that a substantial proportion of very aggressive children and youth have moderately low to surprisingly high levels of popularity among their peers.

Bullying may peak in early adolescence, but these two social worlds of bullying exist as early as kindergarten (Alsaker & Gutzwiller-Helfenfinger, 2010), or in Farmer and colleagues’ study, second grade. The two social worlds of bullying represent two central but seemingly inconsistent views of aggressive behavior: as dysfunctional and maladaptive, or functional and adaptive. As light can be both wave and particle, aggression can be maladaptive or adaptive depending on why the aggression occurs, the time frame (e.g., “good in the short run, but bad

in the long run”), the consequences of aggressive acts, and one’s perspective (Rodkin & Wilson, 2007). Educators and parents need to ask why bullying is working from the perspective of the bully and what goals are being served by bullying behavior, as they will be different for different children.

The Bully-Victim Relationship

Any law enforcement official would quickly want to establish the relationship that might exist between an alleged perpetrator and victim. However, in the area of bullying research, little is known about the relationship between a bully and the child whom he or she targets. Instead, the focus has been on identifying children who fall into *bully*, *victim*, and *bully-victim* categories, and then determining prevalence rates and behavioral characteristics of bullies, victims, and bully-victims (e.g., Cook et al., 2010). This procedure puts bullies and victims into separate boxes and overemphasizes their separateness. In practical terms, this could mean that there is no known relationship between a bully and victim, or something of a random targeting.

Reality is more complicated. Bullies and victims often have a previously existing relationship that presages bullying before it happens, which if known would alert knowledgeable adults about possible trouble spots (Card & Hodges, 2008). One clear predictor of bullying is reciprocated dislike and animosity. Potential bullies, particularly socially connected bullies, actualize angry thoughts into aggressive behavior towards low status peers whom they already dislike, and who dislike them (Hodges, Peets, & Salmivalli, 2009). Socially connected children choose same-sex bullying as part of a struggle for dominance, particularly in the beginning of the school year or between transitions from one school to another, when the social hierarchy is in flux and unpopular children can be targeted (Pellegrini et al., 2010). The bullying behavior of socially connected children is thus quite responsive to changing opportunities in the peer social ecology.

One finding that becomes obvious once bullies and victims are considered as a two-person dyad is that there are a disturbing number of cases, possibly half, where aggressive boys are harassing girls (Berger & Rodkin, 2009; Rodkin & Berger, 2008; Veenstra, Lindenberg, Zijlstra, DeWinter, Verhulst, & Ormel, 2007). Olweus (1993, p. 18) first reported this overlooked finding, writing that “*boys carried out a large part of the bullying to which girls were subjected*” (itals. original): 60% of fifth through seventh grade girls whom Olweus (1993) reported as being harassed said that they were bullied by boys. Similarly, the American Association of University Women (2001, p. 25) reported that 38% of girls who experience sexual harassment “say they first experienced it in elementary school.” Unpopular, rejected-aggressive boys are most likely to harass girls (Rodkin & Berger, 2008), whereas socially connected bullies tend to demonstrate within-sex bullying and dominance against unpopular targets (Pellegrini et al., 2010). Still, boys’ physical and verbal aggression against girls can too often become an accepted part of peer culture. Peer sexual harassment is often seen as a purely adolescent phenomenon, but its origins may be linked to when and how boys harass girls in early and middle childhood (Garandeau, Wilson, & Rodkin, 2010; Hanish, Hill, Gosney, Fabes, & Martin, 2011; Rodkin & Fischer, 2003; Rosenbluth, Whitaker, Valle, & Ball, 2011; Ybarra, Espelage, & Martin, 2011). More generally, gender and sexuality is a hidden underbelly of much bullying, as described in the white paper by Espelage. Any notable difference between

people that can be associated with power differentials, such as religion, disability, or ethnicity, has the potential to be seized upon as an object of harassment.

Peer Relationships That Promote and Prevent Bullying

Peer relationships are like oxygen that allows bullying to breathe and spread; peer relationships can be used as a cudgel, a weapon of shame against victims, but even one good friend to a victim of bullying can help assuage the harmful consequences of being harassed.

Socially marginalized bullies who are also victims, who predominantly aggress in reaction to provocation, stand out through their segregation from most peers as isolates or as members of deviant, peripheral peer cliques. These youth would benefit from services that go beyond bullying-reduction programs per se, such as violence reduction therapies and social skills training (Bierman & Powers, 2009; Cook et al., 2010). Where feasible the social ties of marginalized bullies should be broadened to include a greater variety of peers.

My colleague Ramin Karimpour and I have referred to socially connected bullies as “hidden in plain sight” (Rodkin & Karimpour, 2008) because they are on the one hand more socially prominent than marginalized bullies, yet less likely to be recognized as bullies or as at-risk. Since socially connected bullies affiliate with a wide variety of peers, there is an unhealthy potential for widespread acceptance of bullying in some classrooms and schools. This is what Debra Pepler and colleagues call the *theatre of bullying* (Pepler, Craig, & O’Connell, 2010), encompassing not only the bully-victim dyad, but also children who encourage and reinforce bullies (or become bullies themselves), others who silently witness harassment and abuse, and hopefully still others who intervene to support children being harassed (see also Salmivalli et al., 2010). As Pepler and colleagues (2010, p. 470) write: “bullying is a social event in the classroom and on the playground,” with an audience of peers in almost 90% of observed cases. This silent, mocking audience grows exponentially, in frightening anonymity, with cyberbullying. Thus, the problem of bullying is also a problem of the unresponsive bystander, whether that bystander is a classmate who finds harassment to be funny, or a peer who sits on the sidelines afraid to get involved, or an educator who sees bullying as just another part of growing up.

Socially connected bullies target children who will likely *not* be defended (Card & Hodges, 2008; Pellegrini et al., 2010; Veenstra, Lindenberg, Munniksma, & Dijkstra, 2010), but peers who do intervene in bullying can make a real difference. Socially connected bullies thrive on being perceived as dominant, popular, and cool, which is fed by tacit or overt acceptance by peers. Peers who intervene to stop bullying may be successful on over half of such attempts, but unfortunately these defenders stand up in less than 20% of bullying incidents (Pepler et al., 2010; Salmivalli et al., 2010). *One good friend* can make a crucial difference to children who are harassed. Associations between victimization and internalizing problems (e.g., being sad, depressed, anxious) are minimized for victims who are friends with a non-victimized peer (Hodges, Boivin, Vitaro, & Bukowski, 1999). Even first grade children who have a friend but are otherwise socially isolated seem to be protected from the adjustment problems suffered by other isolated children (Laursen, Bukowski, Aunola, & Nurmi, 2007). Peer relationships are crucial both for the bully who is looking to maintain or acquire social status, and for the child who is looking to cope with, and better yet end, peer harassment.

Classroom and School Climate

With clouds of war gathering, German émigré and child psychologist Kurt Lewin and his colleagues created clubs for 10-yearold boys that were organized in an authoritarian (fascistic) or democratic fashion (Lewin, Lippitt, & White, 1939). Victimization and scapegoating were highest in groups with an *autocratic* atmosphere, with a dominant group leader and a strongly hierarchical structure. Victimization was lowest in groups with a *democratic* atmosphere, where relationships with group leaders were more egalitarian and cohesive.

Classroom and school climates are built by the relationships peers have to one another and to their teachers. These interpersonal bonds need to be healthy, or bullying and antisocial behavior can overpower the learning environment. It's well worth asking whether today's schools are characterized by a democratic or autocratic social climate, and whether differences in school climate are related to bullying. Classroom peer ecologies with more egalitarian social status hierarchies, strong group norms in support of academic achievement and prosocial behavior, and cohesive, positive social ties between children should deprive many socially connected bullies of the peer regard that they require (Ahn, Garandeau, & Rodkin, 2010; Frey, Edstrom, & Hirschstein, 2010; Pellegrini et al., 2010; Rodkin & Gest, 2011; Wilson, Karimpour, & Rodkin, 2011). In contrast, even children who are not themselves bullies will form pro-bullying attitudes in classrooms where bullies are popular (Dijkstra, Lindenberg, & Veenstra, 2008), feeding a vicious cycle of bullying reinforcement and failure to stand up for victims of harassment.

Managing School Social Networks to Prevent and Intervene in Bullying

In a review of bullying-reduction programs, Farrington and Ttofi (2009) found that interventions that explicitly work with peers, such as using students as peer mediators, or engaging bystanders to disapprove of bullying and support victims of harassment, were associated with *increases* in victimization! In fact, of twenty program elements included in 44 school-based programs, work with peers was the *only* program element that was associated with significantly *more* bullying and victimization. (In contrast, there were significant and positive effects for parent training and meetings in reducing bullying.) Still other reviews of bullying intervention programs have found generally weak effects (Merrell, Gueldner, Ross, & Isava, 2008).

These disheartening results speak to the fact that peer influences can be a constructive or destructive force on bullying, and need to be handled with knowledge, skill, and care. Antisocial peer groups can undermine behavioral interventions (Dishion & Tipsord, 2011). The most potentially important peer effects have yet to be studied adequately. For instance, children who are chosen to be peer mediators should probably be identified as popular and prosocial for peer mediation to be effective (Pellegrini et al., 2010; Pepler et al., 2010; Vaillancourt et al., 2010). Some of the most innovative, intensive, grass-roots uses of peer relationships to reduce bullying, such as the *You Have the Power!* Program in Montgomery County, Maryland (Holstein-Glass, Silliman, & Nahin, 2010), are never scientifically evaluated. The final verdict awaits on some promising programs that take advantage of peer relationships to combat bullying, such as the KiVa program of Salmivalli et al. (2010), and the Steps to Respect program of Frey et al. (2010).

Teachers can ask what kind of bully they face when dealing with a concrete victimization problem. Is the bully a member of a group, or a group leader? How are bullies and victims situated in the peer ecology? Educators who exclusively target peripheral, antisocial cliques as the engine of school violence problems may leave intact other groups that are more responsible for mainstream peer support of bullying. A strong step educators could take would be to periodically ask students about their social relationships, taking advantage of increasingly powerful techniques of social network analysis that are becoming more user-friendly to educators (Mulvey & Cauffman, 2001; Rodkin & Hanish, 2007). Of course, these efforts can only work in a larger climate where families and educators teach and model strong moral character to our next generation of Americans. Some additional recommendations are listed below (for more, see Berger, Karimpour, & Rodkin, 2008; Garandeau et al., 2010):

- **Ask students about bullying.** Survey students regularly on whether they are being harassed or have witnessed harassment. Make it easier for students to come to an adult in the school to talk about harassment. Consider what bullying accomplishes for a bully.
- **Ask students about their relationships.** Bullying itself is a relationship-- a destructive, asymmetric relationship. Know who students hang out with, who their friends are, and who they dislike. Know who students perceive to be popular and unpopular. Connect with children who have no friends. School staff vary widely in their knowledge of students' relationships, and tend to underestimate the popularity of aggression among peers.
- **Build democratic classroom and school climates.** Identify student leaders who can encourage peers to stand against bullying. Assess whether student social norms are *really* against bullying. Train teachers to better understand and manage student social dynamics, and to handle aggression with clear, consistent consequences. Master teachers not only promote academic success, they also build relationships, trust, and a sense of community.
- **Be an informed consumer of anti-bullying curricula.** Anti-bullying interventions can be successful, but there are significant caveats (Merrell et al., 2008) Some bullies are challenged in broad domains of developmental functioning. Some programs work well in Europe, but not as well here in the U.S. (Farrington & Ttofi, 2009). Most anti-bullying programs have not been rigorously evaluated, so be an informed consumer when investigating claims of success. Even with a well-developed anti-bullying curriculum, understanding students' relationships at your school is critical.
- **Remember that bullying is also a problem of values.** Implement a character education or socioemotional learning curriculum that is intellectually challenging. Teach children how to achieve their goals by being assertive rather than aggressive. Always resolve conflicts with civility, among and between staff and students. Involve families.

Charles Payne, in his outstanding 2008 book *So Much Reform, So Little Change*, makes the point that even the best, most rigorous and validated intervention won't be successful without appreciation of the weak social infrastructure and dysfunctional organizational environments of some schools. If adult social networks can doom educational reform, then surely youth social networks can as well.

Child and youth peer ecologies can provide resistance or support to adults' best efforts. When popular children engage in or endorse bullying, they send a message to all students that conflicts with basic values of respect and tolerance that we all should share.

The task ahead is to better integrate bullies and the children they harass into the social fabric of the school, to better inform educators of how to recognize, understand, and help guide children's relationships. With guidance from caring, engaged adults, youth can organize themselves as a force that makes bullying less effective as a means of social connection, or as an outlet for alienation. As detailed in the white paper by Limber, clear, enforceable anti-bullying school policies, including strong consequences for bullying, are also critical. The scourge of bullying has no role in the truly democratic, American school.

EFFECTIVE STRATEGIES IN COMBATING BULLYING

Catherine P. Bradshaw and Tracy E. Waasdorp^v

Johns Hopkins Center for the Prevention of Youth Violence,

Johns Hopkins Bloomberg School of Public Health

Bullying is the most common form of victimization experienced by school-aged children (Nansel et al., 2001) and is an increasing national concern. Nearly all states have passed laws specifically related to bullying prevention, some of which encourage the use of programs or strategies to prevent bullying (Limber & Small, 2003). However, the research on this issue is mixed, with some programs producing significant effects on bullying, but others producing only limited impacts. Schools need guidance on which programs to implement, as well as strategies for optimizing program impacts. This report examines the association between bullying and school climate, and summarizes the research on bullying prevention programs and strategies. Gaps in the current research are highlighted, and recommendations are made regarding the implementation of effective bullying and violence prevention programs.

What Is the Link between Bullying and School Climate?

Research on factors influencing children's risk for involvement in bullying often draws upon the social-ecological framework. Based on initial work by Bronfenbrenner (1979), Espelage and Swearer (2004) applied the social-ecological framework to bullying, highlighting the importance of considering context in relation to individual factors. That context includes social and physical aspects of the youth's environment, which influence both the risk for involvement in bullying and the impact of bullying on social-emotional functioning and academic outcomes. In fact, several studies indicate that youth involved in bullying – as either a bully or a victim – have less favorable perceptions of school and feel less connected to their school (O'Brennan, Bradshaw, & Sawyer, 2009; Nansel et al., 2001). The more frequently these children are involved in bullying, the less safe they feel. Importantly, even bystanders are negatively affected by bullying (Stueve et al., 2006).

Researchers have identified a set of social factors that contribute to a "climate or culture of bullying," (Unnever & Cornell, 2003), which includes shared beliefs and attitudes supporting bullying. In these contexts, aggression and peer victimization become the norm. Not surprisingly, so called "disorderly" or disorganized schools and classrooms have higher rates of bullying. Students perceive these schools as less safe and less supportive, which, in turn, can contribute to aggressive retaliation, resistance to reporting bullying incidents to adults, and poor academic performance (Bradshaw, Sawyer, & O'Brennan, 2009; Unnever & Cornell, 2003).

What Are Common Outcomes of Bullying Prevention Programs?

Although researchers generally agree that self-reports are among the most valid indicators of bullying (Furlong et al., 2009), much of the research on the impact of bullying prevention approaches has focused rather narrowly on students' self-reports of bullying and victimization (Ryan & Smith, 2009). Relatively few studies have reported multiple sources of data on bullying, however, some of the more comprehensive studies have examined observational data, peer reports, or teacher ratings. Other program outcomes also have been studied, such as attitudes toward bullying, avoidance of bullying situations, safety, and school climate (e.g., Fonagy, Twemlow, Vernberg, Sacco, & Little, 2005; Frey et al., 2005; 2009). Notably, bullying typically co-occurs with other forms of aggressive and problem behavior (Nansel et al., 2001; O'Brennan et al., 2009). Therefore, programs that have a broader focus on preventing aggressive and disruptive behavior by addressing social-emotional skills, interpersonal conflict, and behavioral inhibition would likely also curb bullying behaviors (for a review, see Wilson & Lipsey, 2007).

What Works in Bullying Prevention and Intervention?

Multi-Tiered Prevention Approaches

A common approach to the prevention of bullying and other emotional and behavioral problems is the three-tiered public health model (Mrazek & Haggerty, 1994; O'Connell, Boat, & Warner, 2009; Walker et al., 1996). This model includes a universal system of support, or a set of activities that affect all students within a defined community or school setting. Layered onto that first tier of support are selected interventions that target a subgroup of at-risk students. A third level of support includes indicated interventions for youth already showing early signs of problem behaviors. For example, a tiered approach might include lessons on social-emotional skill development for all students – thus making it a universal program. In fact, research highlights the importance of providing class time to discuss bullying (Olweus, 1993) and the use of lessons to foster skills and competencies, effective communication, and strategies for responding to bullying (Farrington & Tofi, 2009); such strategies can also have a positive impact on academic and other behavioral outcomes (Durlak et al., in press). Effective classroom management is also critical, as well-managed classrooms are rated as having a more favorable climate, being safer and more supportive, and having lower rates of bullying (Koth, Bradshaw, & Leaf, 2008). At the second tier, selective interventions may include social skills training for small groups of children at risk for becoming involved in bullying. Finally, an indicated preventive intervention (tier 3) may include more intensive supports and programs tailored to meet the needs of students identified as a bully or victim, and the needs of their families (Espelage & Swearer, 2008; Ross & Horner, 2009).

School-Wide Prevention Activities

Consistent with the social-ecological framework (Espelage & Swearer, 2004), schools should address the social environment and the broader culture and climate of bullying (Bradshaw & Waasdorp, 2009). Research documents the importance of school-wide prevention efforts that provide positive behavior support, establish a common set of expectations for positive behavior across all school contexts, and involve all school staff in prevention activities

(Ross & Horner, 2009). Effective supervision – especially in bullying ‘hot spots’ – and clear anti-bullying policies are essential elements of a successful school-wide prevention effort (Olweus, 1993). The playground appears to be a particularly important context for increasing supervision in order to prevent bullying (Farrington & Ttofi, 2009; Frey et al., 2005). Collecting data on bullying via anonymous student surveys can inform the supervision and intervention process (HRSA, n.d.a). These data can identify potential areas for intensive training for school staff, which is an essential element of successful bullying prevention efforts (Farrington & Ttofi, 2009). Data are also critical for monitoring progress toward the goal of reducing bullying (Olweus, 1993).

Involving Families and Communities

Families also play a critical role in bullying prevention by providing emotional support to promote disclosure of bullying incidents and by fostering coping skills in their children.

Parents need training in how to talk with their children about bullying (Lindstrom Johnson et al., in press), how to communicate their concerns about bullying to the school, and how to get actively involved in school-based bullying prevention efforts (Waasdorp, Bradshaw, & Duong, in press). There also are important bullying prevention activities that can occur at the community level, such as awareness or social marking campaigns that encourage all youth and adults – such as doctors, police officers, and storekeepers – to intervene when they see bullying and to become actively involved in school- and community-based prevention activities (HRSA, n.d.a; Olweus, 1993).

Integrating and Sustaining Prevention Efforts

It is also important to consider how schools can integrate prevention efforts with their other existing programs and supports. Research by Gottfredson and Gottfredson (2001) indicates that, on average, schools are using about 14 different strategies or programs to prevent violence and promote a safe learning environment.

This can often be overwhelming for school staff to execute well, thereby leading to poor implementation fidelity. Therefore, schools are encouraged to integrate their prevention efforts so that there is a seamless system of support (Domitrovich et al., 2009), which is coordinated, monitored for high fidelity implementation, and includes all staff across all school contexts. Instead of adopting a different program to combat each new problem that emerges, it is recommended that schools develop a consistent and longterm prevention plan that addresses multiple student concerns through a set of well-integrated programs and services (HRSA, n.d.a).

Such efforts would address multiple competencies and skills in order to prevent bullying, and help students cope and respond appropriately when bullying does occur. The three-tiered public health model provides a framework for connecting bullying prevention with other programs to address bullying within the broader set of behavioral and academic concerns.

What are Some Specific Evidence-Based Bullying Prevention Programs?

Recent research has investigated the overall impact of anti-bullying programs; however, the findings of these meta-analyses have been mixed (e.g., Ferguson, San Miguel, Kilburn, & Sanchez, 2007; Merrell, Gueldner, Ross, & Isava, 2008; Ryan & Smith, 2009; Smith et al.,

2004; Vreeman & Carroll, 2007). To date, the most comprehensive review is Farrington and Ttofi's (2009) Campbell Systematic Review of 53 rigorous evaluations and randomized trials. The majority of these studies were conducted outside of the US or Canada (66%), and over a third of these programs were based in part on the work of Olweus (1993). Farrington and Ttofi found that the programs, on average, were associated with a 20% to 23% decrease in perpetration of bullying, and a 17% to 20% decrease in victimization. The effects generally were stronger in the non-randomized controlled trial designs, suggesting that the more rigorous the study design, the smaller the effects on bullying were (Farrington & Ttofi, 2009).

A number of factors were associated with the effectiveness of these programs. For example, Farrington and Ttofi (2009) found that the most effective elements were the use of parent training activities, meetings, and information; high levels of playground supervision; use of consistent disciplinary methods; classroom management strategies; classroom and school-wide rules related to bullying; and training of teachers. Aspects of the student and teacher training, including the amount of time and the intensity of the training, were also positively associated with the efficacy of the programs. Consistent with previous studies (Olweus, 2005; Smith, 1997), their findings also support the use of multicomponent prevention approaches. The impacts appeared to be largest among older children (ages 11-14) relative to younger children. It is important to note that, unfortunately, the programs were generally more effective in Europe than in the US or Canada.

The most extensively researched program is the **Olweus Bullying Prevention Program**, which was developed by Olweus and colleagues (Olweus et al., 2007). Much of the research demonstrating the effectiveness of this multicomponent, school-wide prevention model was conducted in Norway (e.g., Olweus, 2005; Olweus, Limber, & Mihalic, 1999), with some studies conducted within the US (e.g., Bauer, Lozano, & Rivara, 2007; Limber et al., 2004). The Olweus Bullying Prevention Program includes school-wide components, classroom activities and meetings, targeted interventions for students identified as bullies or victims, and activities aimed at increasing community involvement (e.g., parents, mental health workers). Other derivations of this program also have been shown to be effective at preventing bullying in North America (e.g., Pepler et al., 2004). Farrington and Ttofi (2009) concluded that programs that were conceptually based on the Olweus Bullying Prevention Program were the most effective. Another evidence-based bullying prevention program is **Steps to Respect**, which targets students in grades 3-6 (Frey et al., 2005). This multicomponent program includes a school-wide prevention effort, parent activities, classroom-focused lessons, and targeted activities for children involved in bullying, which are facilitated by counselors. Randomized trials of Steps to Respect have indicated significant impacts on bullying-related attitudes and observations of bullying, but not on student self-reports of bullying (Frey et al., 2009; 2005).

Programs aiming to prevent violence and disruptive behaviors and promote a positive school climate can also impact bullying. For example, recent findings indicate that the school-wide **Positive Behavioral Interventions and Supports** (PBIS; Sugai & Horner, 2006) model has a significant impact on teacher reports of bullying and rejection (Waasdorp, Bradshaw, & Leaf, 2011), as well as on school climate and discipline problems (Bradshaw, Koth, Thornton, & Leaf, 2009; Bradshaw, Mitchell, & Leaf, 2010; Horner et al., 2009). Social-emotional learning programs, such as the **Promoting Alternative Thinking Strategies** (PATHS; Greenberg, Kusché, Cook, & Quamma, 1995), and classroom management strategies, such as the **Good Behavior Game** (Ialongo, Werthamer, & Kellam, 1999), have demonstrated impacts on a range of aggressive-disruptive behavior problems. In addition, the **Coping Power Program**

(Lochman & Wells, 2004), which targets aggressive youth and their parents, also has demonstrated significant effects on aggressive behavior, social interactions, and disruptive behavior. Therefore, schools are encouraged to implement these more comprehensive programs to address a range of problem behaviors, including bullying (for a review, see Wilson & Lipsey, 2007).

What Strategies May Be Ineffective or Potentially Damaging?

Given the complex nature of bullying, there are some strategies that have been shown to be ineffective or potentially harmful for students. One of these approaches is youth- or peer-facilitated programs, such as peer mediation, peer-led conflict resolution, and peer mentoring.

In fact, research by Farrington and Ttofi (2009) indicated that many programs that used these peer-facilitated approaches actually resulted in increases in victimization. Moreover, studies on youth violence and delinquency prevention (Dodge, Dishion, & Lansford, 2006) suggest that grouping children who bully together may actually reinforce their aggressive behaviors and result in higher rates of bullying. In these contexts, a contagion process occurs, whereby the bullies learn from each other and are reinforced for their aggressive behavior. Furthermore, conflict resolution, even when facilitated by adults, is not typically recommended in situations of bullying, as it suggests a disagreement between two peers of equal status or power, rather than an instance of peer abuse (HRSA, n.d.b).

There is also little evidence that brief assemblies or one-day awareness raising events are sufficient for changing a climate of bullying or producing sustainable effects on bullying behavior (HRSA, n.d.b). Rather, as was found by Farrington and Ttofi (2009), multicomponent programs hold the greatest promise.

Finally, zero-tolerance policies, which mandate suspensions for children who bully, are a common response to bullying and other forms of school violence (APA, 2008).

Although ensuring the safety of the victim is paramount, and a consistent discipline procedure is strongly recommended (Farrington & Ttofi, 2009), zero-tolerance policies may result in underreporting of bullying incidents because they are perceived as too harsh or punitive. Furthermore, there is limited evidence that they are effective in curbing aggressive or bullying behavior (APA, 2008), as many children who bully may themselves be victims and may have other behavioral, social, or emotional problems requiring intervention (Nansel et al., 2001; O'Brennan et al., 2009; Swearer, Espelage, Vaillancourt, & Hymel, 2010). Therefore, schools and districts should be cautious in the use of these approaches, as they may do more harm than good.

What Factors Are Important to Consider When Implementing Prevention Programs?

There has been a movement toward the use of 'packaged' evidence-based prevention programs over the past several years. The work by Farrington and Ttofi (2009) sheds some light on the most efficacious elements of multicomponent bullying prevention programs; however, schools should be cautious when implementing just a few components of a program, as they may not produce the same effects when implemented in isolation. The cost and related resource

needs may also serve as barriers to implementing the more rigorously tested evidence-based prevention programs. Getting ‘buy-in’ from all students and staff is critical to the success of any prevention effort, especially for multicomponent school-wide models, which can be difficult to implement with high fidelity (Bradshaw, Koth et al., 2009; Durlak et al., in press).

Research highlights a number of contextual factors, like principal leadership, staff attitudes toward the program, and the availability of resources that impact implementation quality (Domitrovich et al., 2008; Hong, 2009). Therefore, considerable pre-implementation planning is needed to garner staff support and buy-in for the program and to integrate the new program with existing supports and services (Limber, 2004).

Once implemented, the collection of fidelity and outcome data is critical to ensuring high quality implementation, tracking progress towards outcomes, and promoting sustainability. Unfortunately, most programs lack valid and efficient tools for tracking implementation fidelity, and regular assessments of self-reports of bullying can be costly and burdensome for some schools. Many schools find it helpful to form a team to lead the implementation and help with the integration of programs and the program monitoring process (Limber, 2004).

An implementation specialist or ‘coach’ can also be helpful in ensuring high quality implementation of bullying prevention programs. Changing school climate and the culture of bullying is difficult and requires sustained and intensive commitment from all students, staff, families, and the community. The development of an implementation infrastructure, at the school, district, and state level, is essential to scaling up the available research-based programs (for example, see Barrett, Bradshaw, & Lewis-Palmer, 2008).

What Additional Research Is Needed to Improve Our Understanding of the Most Effective Strategies for Combating Bullying?

Additional research is needed in several areas related to bullying prevention. As noted above, there are relatively few prevention programs, tested through rigorous research designs, which have demonstrated significant impacts on bullying among US students (Farrington & Ttofi, 2009; Merrell et al., 2008).

Further research is needed on bullying prevention programs to determine their effectiveness in diverse contexts and with different populations, particularly in urban schools and with ethnic minority students and students with disabilities.

The impact of programs also likely varies based on student factors, such as the age or gender of the child, the type of involvement in bullying they experienced (e.g., bully, victim, or both bully and victim), as well as the form of bullying (e.g., cyberbullying or bullying related to perceived sexual orientation or gender non-conformity).

Although the rates of bullying tend to peak during middle school, very few bullying prevention or intervention programs have been developed and tested on high school students.

Additional research is also needed to determine which program components are critical for success, and what factors are important in predicting high quality program implementation. Unfortunately, there have been no cost-benefit analysis studies conducted of bullying prevention programs, although such work is available for some of the more general youth violence prevention programs (see Aos, Lieb, Mayfield, Miller, & Pennucci, 2004).

Studies are also needed to determine the impact of the relatively recently enacted state-level bullying policies on rates of bullying. Moreover, the policies should have an increased

focus on staff training and the use of research-based prevention efforts (Limber & Small, 2003). What is clear is that the passage of these policies signals to educators, parents, and the community that bullying is a major concern - one with potentially serious consequences for students and the school environment (Swearer et al., 2010).

REDUCING THE EFFECTIVENESS OF BULLYING BEHAVIOR IN SCHOOLS^{VI,VII}

OSEP Center on Positive Behavioral Interventions and Supports

www.pbis.org

Prepared by

George Sugai

University of Connecticut

Rob Horner

University of Oregon

Ensuring that children and youth have safe, caring, and respectful places to learn and socialize has been among the top concerns of the general public over the past 40 years (Bushaw & Lopez, 2010). However, effective classroom management and school discipline receive relatively minor attention in many teacher preparation programs and remain in the informal shadows of the academic mission of many schools (Baker, 2005; Oliver & Reschly, 2007; Siebert, 2005). The assumption is that students will come to school ready to learn, adequately prepared to navigate the classroom expectations, and have the social skills to establish lasting relationships with others. In addition, disciplinary consequences and policies are used to “control and punish” norm-violating actions. At best, learning the school and classroom behavioral expectations is informal and trial and error at best.

Calls for effective behavior management and better discipline spike when a school shootings occurs, a student takes her own life, or a youth hurts his classmate. Our immediate reactions are to demand more punishment-oriented consequences, greater student accountability and personal responsibility, and intensive screening for identification. Concerns about recent tragic bullying events and general lack of civility of children and youth have given high priority to bully proofing and violence prevention initiatives.

Although such efforts are understandable and admirable, they are not implemented for long, student behavior does not improve, and school climate remains negative and control-oriented. A major message of this paper is that the challenge is not that we don’t know the characteristics of effective violence prevention strategies, but that we need to implement a systemic framework or process through which these strategies might actually prevent the development and occurrences of violent behavior for all students.

The purpose of this document is to provide an overview of how school-wide positive behavioral interventions and supports (PBIS) can provide such a framework for improving the effectiveness, efficiency, and relevance of practices that can help prevent school violence and bullying behavior, in particular. This overview is organized around eight main questions.

1. What Do We Know about Preventing Violence in Schools?

Decades of research provide excellent guidance on what competent school environments look like and do to prevent the development and occurrence of violent behavior, including bullying behavior, in schools and neighborhoods (e.g., Biglan, 1995; Gottfredson, 1997; Gottfredson, Gottfredson, & Hybl, 1993; Mayer, 1995; Morrison, Furlong, & Morrison, 1997; Tolan & Guerra, 1994; Walker, Ramsey, & Gresham, 2004). In general, effective schools formally invest in the following protective activities:

1. School-wide curriculum that emphasizes targeted social skills instruction.
2. Establishment of positive school and classroom social cultures where teaching and learning are emphasized.
3. Challenging and engaging instructional practices that effectively maximize academic success for all students.
4. Continuous, positive, and active supervision and monitoring of student behavior and learning.
5. Regular, frequent, and positive acknowledgements and reinforcement for student displays of academic and social behavior success.
6. Active involvement of all students and family, faculty, and community members.
7. Multi-year and multi-component approaches to implementation.
8. Adults who model the same positive social behaviors and values expected of students.

2. What Is “Positive Behavioral Interventions and Supports?”

To maximize the impact of effective violence prevention strategies, careful attention must be directed to the systemic supports that enable accurate, durable, and scalable implementation (Fixsen et al., 2005). In 1996, the U.S. Congress reauthorized the Individuals with Disabilities Education Improvement Act (IDEIA), and included authority to establish the National Technical Assistance Center for Positive Behavioral Interventions and Supports (PBIS, www.pbis.org).

It is important to understand that PBIS is NOT a packaged curriculum, scripted intervention, or manualized strategy. Rather, PBIS IS a prevention-oriented multi-tiered framework for school personnel to (a) organize evidence-based practices, (b) implement those practices with high fidelity, and (c) maximize academic and social behavior outcomes for all students (Sugai et al., 1999).

3. How Does School-Wide PBIS Relate to the Prevention of Bullying Behavior?

PBIS begins with the premise that all students should have access to positive behavioral supports to prevent the development and occurrence of problem behavior, including bullying. To avoid stigmatizing any student, PBIS emphasizes what a student does and where it occurs. Instead of labeling a student as a bully, victim, perpetrator, or bystander, the emphasis is on

labeling what the student does, for example, name-calling, teasing, intimidation, verbal aggression, and cyberharassment. Bullying behavior is always described in the context or setting in which it occurs, for example, cyberspace, hallway, dance, field trip, bus, etc.

From a PBIS perspective, successful prevention of bullying behavior is linked directly to teaching adults and students (a) what bullying looks like, (b) what to do before and when bullying behavior is observed, (c) how to teach others what to do, and (d) how to establish a positive and preventive environment that reduces the effectiveness of bullying behavior (Ross, Horner, & Stiller, 2009).

4. What Is the PBIS Approach to Preventing Bullying Behavior?

PBIS takes a multi-tiered responsiveness-tointervention approach to preventing bullying behavior (Bradley, Danielson, & Doolittle, 2007; Sugai & Horner, 2009), which is derived directly from the “3-tiered” public health prevention logic (Walker et al., 1996).

At Tier I, all students and staff are taught directly and formally about how to behave in safe, respectful, and responsible ways across all school settings. The emphasis is on teaching and encouraging positive social skills and character traits. If implemented well, most students will benefit and be successful (Lewis & Sugai, 1999; Taylor-Greene et al., 1997; Sugai et al., 1999).

At Tier II, students whose behaviors do not respond to Tier I supports are provided additional preventive strategies (Crone, Hawken, & Horner, 2010; Fairbanks, Sugai, Guardino, & Lathrop, 2007) that involve (a) more targeted social skills instruction, (b) increased adult monitoring and positive attention, (c) specific and regular daily feedback on their behavioral progress, and (d) additional academic supports, if necessary.

At Tier III, students whose behaviors do not respond to Tier I and II supports are provided intensive preventive strategies (Crone & Horner, 2003; Eber, Sugai, Smith, & Scott, 2002; Walker, Ramsey, & Gresham, 2004) that involve (a) highly individualized academic and/or behavior intervention planning; (b) more comprehensive, person-centered and function-based wraparound processes; and (c) school-family-community mental health supports.

From a prevention and responsiveness-tointervention perspective, not all students respond equally to bully prevention strategies because of a variety of risk and protective factors, for example, behavioral learning history, socio-economic status, social skill competence, academic achievement, disability, peer and family influences (Biglan, 1995; Mayer, 1995; Spivak & Prothrow-Stith, 2001; Walker, Ramsey, & Gresham, 2004). Effective Tier I prevention programs are intended to support most students and then to identify those who may require more intensive and specialized assistance (Tier II and III). This logic is important for students who engage in bullying behavior as well as those who are targets and observers of bullying behaviors. It is important to note that increasing the severity and number of more punishing consequences is not emphasized.

Many evidence-based practices for preventing bullying behavior are available (Bradshaw, Johnson, 2011; Elliott, Hamburg, & Williams, 1998; Espelage & Swearer, 2003; Lipsey & Wilson, 1993; Mayer, 1995; Morrison, Furlong, & Morrison, 1997; Olweus, Limber, & Mihalic, 1990; Ross & Horner, 2009); however, their effectiveness and durability are dependent upon the use of good data systems, efficient progress monitoring tools, competent school personnel, on-going and embedded professional development, formal coaching and

coordination supports, and adequate school and district systems to sustain meaningful outcomes with accurate implementation (Fixsen et al., 2005; PBIS Implementation Blueprint, 2010; PBIS Evaluation Blueprint, 2009).

5. What Costs Are Associated with Implementing School-wide PBIS?

The National PBIS Center is funded by the Office of Special Education Programs in the U.S. Department of Education to disseminate and provide technical assistance to schools, districts, and states. The PBIS Center's website (www.pbis.org) provides a comprehensive collection of free and downloadable materials related to the multi-tiered approach to PBIS, including bullying behavior prevention.

Contact information for a network of state and district implementation efforts is also available at the website. Some states have formalized their training and professional development efforts such that costs are minimized. PBIS state coordinators can be contacted for more information about school and district implementation opportunities and costs.

Although specific trainer costs may vary depending on whether a state or district has established its own training capacity or relies on external trainers, a school's major costs will be associated with professional development days for a PBIS leadership team to develop, implement, and monitor the progress of a PBIS action plan (e.g., substitute teachers). Professional development costs depend on demographic characteristics (e.g., school and district size, number of schools, prior PBIS experiences). During the initial implementation years, schools should expect each team member to participate in 4 to 6 full days of professional development, and implementation action planning (PBIS Professional Development Blueprint, 2010).

Because implementation occurs in phases, the first two to three years are focused on establishing the working infrastructure and capacity for initial implementation of the three-tiered prevention continuum, especially Tier I supports. Over time, action planning shifts to sustaining and improving implementation outcomes, behavioral capacity, and efficiency, and addressing other behavioral needs.

Most importantly, before implementing any PBIS component, schools, districts, and states are encouraged to complete a self-assessment audit of existing behavioral initiatives, programs, interventions, and priorities. The goal is to discontinue ineffective or poorly implemented practices, adjust effective initiatives to improve efficiency and durability, and combine or integrate efforts that have similar outcome expectations and objectives. PBIS implementation cannot be an "add-on" to existing initiatives and programs. Instead, existing resources are re-invested in the smallest number of the most effective, efficient, and relevant practices and initiatives possible. Doing a few things really well is preferred to doing many things partially, or not at all.

PBIS Steps to Addressing Bullying Behavior at School
Step 1. If bullying behavior is identified as a concern, members of a PBIS school leadership team would start by examining their discipline data to determine How often what bullying behaviors (e.g., verbal/physical aggression, intimidation, teasing) were occurring.

• Where those behaviors were being reported (e.g., hallways, parking lots, cyberspace). • How many and which students are involved in displays of bullying behavior (including students who are targets and/or observers of bullying behavior). • Which staff members have been involved in bullying behavior incidents. • When during the day (time/period) and week are bullying behavior being reported.
PBIS Steps to Addressing Bullying Behavior at School
Step 2. A PBIS school leadership team would examine the extent to which Tier I practices and systems are being implemented accurately, fluently, and school-wide. The focus is on the extent to which staff members have • Taught, provided practice for, and acknowledged the behaviors that represent three to five positive school-wide behavioral expectations (e.g., “respecting self, others, and environment;” “safety, responsibility, and honor”). • Actively and positively supervised all students across all school settings. • Had high rates of positive interactions and contact with all students. • Arranged their instruction so all students are actively academically engaged, successful, and challenged.
Step 3. To address bullying behaviors at Tier I, all students and staff would be taught a common strategy for preventing and responding to bullying behavior: • How to avoid situations where bullying behavior is likely. • How to intervene and respond early and quickly to interrupt bullying behavior, remove the social rewards for bullying behavior, and prevent bullying behavior from escalating. • How to remove what triggers and maintains bullying behavior. • How to improve the accuracy, fluency, and sustainability of implementation efforts. • What to do when prevention efforts do not work. • How and what to report and record when a bullying behavior incident occurs.
Step 4. If Steps 1 through 3 are done well, a relatively small proportion of students (initiators, targets, bystanders) will require more than Tier I supports. These students should not receive more of the same ineffective strategies, especially, more severe consequences. Instead, students whose bullying behavior does not improve should be considered for Tiers II and III supports. • These supports would be initiated by increasing consideration of behavioral function or purpose (e.g., “bully behavior results in access to bystander, target, and/or adult attention;” “target behavior results in access to peer and/or adult attention;” “bystander behavior results in access to initiator attention”). • Based on the function of a student’s behavior, students would (a) begin the day with a check-in or reminder about the daily expectations; (b) be more overtly and actively supervised; (c) receive more frequent, regular and positive performance feedback each day; and (d) conclude each day with a checkout or debriefing with an adult. • More intensive supports would be highly individualized, multi-disciplinary, trans-situational (i.e., school, family, community), and long-term.
Step 5. Improving and sustaining implementation of an effective intervention or practice requires that • Accuracy and fluency of implementation are monitored frequently and regularly. • Behavioral data are reviewed regularly. • Intervention features are adapted to improve outcomes and sustain implementation. • Efficient and expert capacity are established to enable consideration of new or other behavioral concerns (scaling and continuous regeneration).

6. Does PBIS Work Better with Different Groups, Settings, or Contexts?

The research base for PBIS is established and expanding (e.g., Bradshaw, Mitchell, & Leaf, 2010; Horner, Sugai, & Anderson, 2010; Horner et al., 2009; Safran & Oswald, 2003). In general, experimental and quasi-experimental studies have demonstrated that when implemented with fidelity, school-wide PBIS is associated with improvements in perceived school health and safety; decreases in disciplinary referrals, detentions, and suspensions; increases in academic achievement; and improvements in concerns related to over-representation and disproportionality for students with disabilities and of color.

Although PBIS implementation has generally occurred at the elementary and middle school levels, high school applications are expanding. In general, the elements, processes, practices, and systems of PBIS are similar across all school levels; however, the specific appearance and implementation characteristics vary based on developmental, cultural, linguistic, organizational, etc. features of individual schools and communities (Flannery et al., 2009).

7. What Does School-wide PBIS Look Like When Bullying Behavior Needs to be Addressed?

By investing in the implementation of multi-tiered prevention frameworks, like PBIS, schools are creating school cultures that prevent the development and occurrences of bullying behavior. However, if a school suspects that bullying behavior might be becoming problematic, a team-based and data-driven problem-solving process is initiated. The following table summarizes the key features of this process.

8. Where Can More Information About PBIS Be Found?

Information about PBIS can be obtained from a number of sources:

- National Center on Positive Behavioral Interventions and Supports (www.pbis.org)
- Office of Safe and Drug Free Schools (www.ed.gov/osdfs)
- Office of Special Education Programs (www.ed.gov/osers/osep)
- Individual State Departments of Education

BULLYING AND THE LESBIAN, GAY, BISEXUAL, TRANSGENDER, QUESTIONING (LGBTQ) COMMUNITY

Dorothy L. Espelage

University of Illinois, Urbana-Champaign

What Do We Know About Rates of Bullying for LGBTQ Students?

A large percentage of bullying among students involves the use of homophobic teasing and slurs, called homophobic teasing or victimization (Poteat & Espelage, 2005; Poteat & Rivers, 2010).

Bullying and homophobic victimization occur more frequently among LGBT youth in American schools than among students who identify as heterosexual (Birkett, Espelage, & Koenig, 2009; Kosciw, Greytak, & Diaz, 2009). A recent nationwide survey of LGBT youth reports that 84.6% of LGBT students reported being verbally harassed, 40.1% reported being physically assaulted at school in the past year because of their sexual orientation (Kosciw, Greytak, Diaz, & Bartkiewicz, 2010). A population-based study of over 200,000 California students found that 7.5% reported being bullied in the last year because they were “gay or lesbian or someone thought they were” (O’Shaughnessy, Russell, Heck, Calhoun, & Laub, 2004, p. 3). Of note, among sexual minority youth, transgender youth remain an especially understudied and underserved population who are often victimized because of their gender expression (Kosciw et al., 2009).

Even without being a direct target of homophobic bullying, a student may feel isolated from friends and teachers because of the anti-gay attitudes and behaviors present in schools; 91.4% of a LGBT middle/high school sample reported that they *sometimes* or *frequently* heard homophobic remarks in school, such as “faggot,” “dyke,” or “queer.” Of these students, 99.4% said they heard remarks from students and 63% heard remarks from faculty or school staff (Kosciw & Diaz, 2006; Kosciw et al., 2008).

The pervasiveness of anti-gay language in schools suggests that most school environments are hostile for LGBT students and create negative environments for their heterosexual peers as well (Swearer, Turner, Givens, & Pollack, 2008).

Are LGBTQ Students More at-Risk for Certain Outcomes Related to Bullying Than Their Heterosexual Peers?

Bontempo and D’Augelli (2002) found that LGB youth were at higher risk for school victimization and health risk behaviors such as substance abuse, sexual risk-taking, and mental health issues than their non-LGB peers. In addition, LGB youth who were victimized reported more risky behaviors than non-victimized LGB youth.

School Engagement

According to a 2003 survey of Massachusetts high school students, individuals who identified as LGB were nearly five times as likely as students who identified as heterosexual to

report not attending school because of feeling unsafe (Massachusetts Youth Risk Behavior Survey, 2003).

A recent nationally representative survey reported that 29.1% of LGBT students missed a class at least once and 30.0% missed at least one day of school in the past month because of safety concerns, compared to only 8.0% and 6.7%, respectively, of a national sample of secondary school students (Kosciw et al., 2010).

Also, in this sample, the reported grade point average of students who were more frequently harassed because of their sexual orientation or gender expression was almost half a grade lower than for students who were less often harassed. LGBT students also tend to have more negative school attitudes (Espelage, Aragon, Birkett, & Koenig, 2008; Russell et al., 2001).

Suicidal Ideation/Attempts

Suicide among sexual minority youth is a major public health concern. A number of studies have reported high rates of suicide attempts among sexual minority youth (D'Augelli & Hershberger, 1993; D'Augelli, Hershberger, & Pilkington, 2002; Espelage et al., 2008; Paul et al., 2002; Safren & Heimberg, 1999); and these youth were significantly more likely to be at risk of suicidal completion than heterosexual youth (Eisenberg & Resnick, 2006; Remafedi et al., 1998).

Child Welfare League of America (2009) found that in 2005, 45% of gay, lesbian, or bisexual youth attempted suicide, compared with eight percent of heterosexual youth. However, on a positive note, when school climate is perceived as positive, it serves to buffer against the experience of negative psychological and social concerns among sexual minority youth (Espelage et al., 2008).

That is, LGB and sexually questioning students who had experienced homophobic teasing, but perceived their school as positive, reported less depression, suicidality, and alcohol and drug use than LGB and questioning students who were bullied and in a negative school climate.

What Challenges Do LGBTQ Students Face Around Bullying That Are Unique from Other Populations?

Sexual minority youth frequently struggle with rejection from their parents, peers, and teachers, as well as homophobia in society, which put them at greater risk for depression, which can lead to self-destructive behavior such as suicide, especially if they are bullied frequently. In addition, students are coming out at younger ages and in higher numbers than in previous generations (Floyd & Bakeman, 2006).

However, they are coming out during middle school when attitudes about same sex attraction are less favorable among early adolescents than as students mature (Heinze & Horn, 2009; Horn, 2006; Poteat, Espelage, & Koenig, 2009). For example, in a study of middle and high school students, 30% of 7th graders (10.8% of 12th graders) indicated that they would not remain friends with someone if they disclosed that they were gay (Poteat et al., 2009). Further, 44.5% of 7th graders (20.6% of 12th graders) would prefer to attend a school where there were no gay or lesbian students. These findings suggest that LGBT students are likely to use sources of support – friends – when they risk disclosing their sexual orientation.

Many LGBTQ students also report that school personnel are perpetrators of homophobic remarks in school – nearly two-thirds (63%) of LGBTQ students in the GLSEN's National

School Climate Survey reported hearing homophobic remarks from school staff (Kosciw et al., 2008) and teachers intervene less when homophobic remarks are made in comparison to racist and sexist remarks (Kosciw et al., 2008).

Moreover, lack of response from other students and teachers to homophobic remarks plays a role in maintaining a school environment that is unsupportive of sexual minority students (Espelage & Swearer, 2008) and compromises their basic rights to safety and an education (Bagley & D'Augelli, 2000; Nichols, 1999).

Indeed, LGBT students typically receive little-to-no protection or support from school policies or administration (Beach et al., 1993; Greydanus & Dewdney, 1985; Kosciw et al., 2010). In a nationwide survey of state and local laws, 42 states were given failing grades for not having sufficient sexuality education, safe school laws protecting students based on sexual orientation, presence of gay straight alliances in schools, and state and local laws protecting the rights of LGB students (Kosciw, 2004).

- Only sixteen states prohibit discrimination or harassment in schools on the basis of sexual orientation.
- Thirty-three states have enacted antibullying/harassment laws that **do not protect** LGBT students

It is obvious that many students who are LGBT or questioning their sexual orientation are spending their childhood and adolescence in schools that lack accurate information, positive role models, or support groups (Bailey & Zucker, 1995; MufozPlaza, Quinn, & Rounds, 2002).

Are There Examples of Strategies, Services, and/or Programs That Are Effective for Preventing and Intervening in Bullying for LGBT Students?

Russell, Kosciw, Horn, and Saewyc (2010) in their "Social Policy Report: Safe Schools Policy for LGBTQ Students" highlight four practices that have shown to promote safety and well-being for LGBTQ youth in schools. These are elaborated here:

Practice #1: School nondiscrimination and anti-bullying policies that specifically include actual or perceived sexual orientation or gender identity or expression (Russell & McGuire, 2008).

- LGBTQ students in states with comprehensive, enumerated safe school laws reported hearing fewer homophobic remarks in school, experienced lower levels of harassment and assault based on sexual orientation or gender expression than students in states with no law or in states with a non-enumerated anti-bullying law and fewer suicidal attempts (Goodenow et al., 2006; Kosciw et al., 2008).

Practice #2: Teachers receive training and ongoing professional development on how to intervene when homophobic teasing occurs.

- Students feel safer when they report that their teachers intervene to stop harassment (O'Shaughnessy et al., 2004).

- Two recent evaluations showed that teacher training around LGBT issues and creating safer school environments for LGBTQ students (Greytak & Kosciw, 2010; Horn & Gregory, 2005).

Practice #3: Presence of school-based support groups or clubs (e.g., gay-straight alliances (GSAs)).

- Students in schools with GSAs reported fewer homophobic remarks, less harassment and bullying based on sexual orientation or gender identity, were less likely to miss school because of feeling unsafe, and were more likely to feel a positive school sense of belonging (Kosciw et al., 2008).
- Szalacha (2003) found in a Massachusetts statewide study found that the presence of a GSA was the most predictive factor in perceived school safety amongst LGB and heterosexual students.
- LGBTQ students who attend schools with Gay-Straight Alliances (GSAs) and other support groups report greater perceptions of safety and lower levels of victimization (California Safe Schools Coalition, 2004; Goodenow et al., 2006; Russell, Muraco, Subramaniam, & Laub, 2009).
- A recent study showed that among heterosexual youth, those who had at least one LG friend were less likely to tolerate unfair treatment toward LG peers (Heinze & Horn, 2009).
- Dialogue groups also can provide opportunities for positive intergroup interactions among peers at school (Candelario & Huber, 2002; Portman & Portman, 2002).

Practice #4: Inclusion of LGBTQ role models or issues in school curricula, including bullying-prevention programming, and access to information and resources through the library, school-based health centers, and other avenues.

- When students know where to get information and resources for LGBTQ issues and if they have someone to talk to at their school then they feel safer (O'Shaughnessy et al., 2004).
- School-based programs that focus on a range of issues such as raising cultural awareness or facilitating individual identity development, building connections between students and their cultural community, or promoting social action to counter prejudice and discrimination are likely to reduce bullying directed toward LGBTQ students (Espelage & Horne, 2008).
- In a study of 23 comprehensive anti-bullying programs aimed at middle and high school students, none of them covered issues of sexual orientation, homophobia, sexual harassment, and sexual violence sufficiently enough to warrant any efficacy (Birkett, Espelage, & Stein, 2008).

How Can Parents, Teachers, Community Leaders, Policy-Makers, and Educators Help to Reduce School Bullying in LGBTQ Community?

1. Support legislation that provides funding to implement anti-bullying policies and that specifically include protections based on students' actual or perceived sexual orientation and gender identity. :
2. Support research on bullying among lgbtq students.
3. Support bullying prevention programs that address homophobia.

BULLYING AND STUDENTS WITH DISABILITIES*A Briefing Paper from the National Council on Disability****Jonathan Young, Ph.D., J.D.***

Chairman, National Council on Disability

Ari Ne’eman

Vice Chair for Engagement, National Council on Disability

Sara GelserMember, National Council on Disability^{viii}

Like bullying in general, bullying of students with disabilities represents both a civil rights and public health challenge. Amongst the possible effects of bullying the U.S. Department of Education (ED, 2010) includes lowered academic achievement and aspirations, increased anxiety, loss of self-esteem and confidence, depression and post-traumatic stress, deterioration in physical health, self-harm and suicidal thinking, suicide, feelings of alienation, absenteeism and other negative impacts, both educational and health related. While both students with and without disabilities face significant negative emotional, educational and physical results from bullying, students with disabilities are both uniquely vulnerable and disproportionately impacted by the bullying phenomenon. Unaddressed bullying of vulnerable students can be expected to have serious negative impacts on the school experiences of all children – social impacts can be expected in addition to individual impacts. Despite this, there exists a dearth of both research and policy focusing on eliminating the bullying of students with disabilities. Furthermore, evidence suggests that existing legal and policy tools available to address bullying against students with disabilities remain significantly underutilized. Additional focus is needed on the bullying of students with disabilities, both as part of a general strategy of bullying prevention efforts and as a specific area of focus in policy and practice.

Background

In 1970, only one in every five children with disabilities received a public education and many states had laws specifically excluding particular disability categories (i.e., children who were deaf, blind, with intellectual disabilities, or emotional disturbance) from public education (ED, 2010). As a result of landmark court cases such as *PARC v. Pennsylvania* (1971), it was established that the 14th Amendment’s equal protection clause required that students with disabilities have the same opportunity to receive a free and appropriate public education as students without disabilities and that, wherever possible, placement in a regular public school class should be the preference. Public Law 94-142 (1975), known then as the Education for All Handicapped Children Act and today Public Law 108-446, the Individuals with Disabilities Education Improvement Act (IDEA) of 2004, created both a legal and funding infrastructure to help ensure that students with disabilities would enjoy the right to a “free and appropriate public education” in the “least restrictive environment.” As a result, many more students with disabilities began to attend and be educated in general education schools and classrooms and thus interacted more with other students.

Research confirms that students with disabilities benefit from being included in the same school settings as their non-disabled peers and that segregated programs fail to demonstrate greater effectiveness (Lipsky, 1997; Buckley, 2000; and Sailor, 2002).

Furthermore, research suggests that students without disabilities may also benefit from inclusion and that, when properly implemented, inclusion of students with disabilities does not negatively impact student test scores, grades, the amount of allocated and engaged instructional time or the rate of interruption to planned activities (York, Vandercook, MacDonald, Heise-Neff, and Caughey, 1992). Despite this, the increased inclusion of students with disabilities, while the right policy and legal decision, necessitates additional efforts to ensure welcoming school environments for students with disabilities.

As demonstrated by both the all too frequent bullying experiences students with disabilities continue to face and the slow progress in fully integrating students with disabilities in public schools (NCD, 2008) across the country, such welcoming environments have not always been forthcoming.

Literature Review

Studies show that students with visible and non-visible disabilities are subject to more bullying than non-disabled peers (Carter and Spencer, 2006). Bullying is frequently a direct result of a student's disability (Whitney, Smith & Thompson, 1994). Students with disabilities are disproportionately likely to face peer rejection, a significant risk factor for victimization (Martlew & Hodson, 1991; Whitney, et al, 1994; and Hodges and Perry, 1996). Many students with disabilities have significant social skills challenges, either as a core trait of their disability or as a result of social isolation due to segregated environments and/or peer rejection. Such students may be at particular risk for bullying and victimization. For example, Little's (2002) study of U.S. mothers found that 94% of children with a diagnosis of Asperger's Syndrome faced peer victimization, including emotional bullying (75%), gang attacks (10%) and nonsexual assaults to the genitals (15%). Clearly it is important to avoid glossing over physical assault, theft, sexual abuse or other crimes by calling them "bullying."

Other research (Siebeker, Swearer, and Lieske, 2005; and Regional Education Laboratory, 2010) has indicated that students with a wide range of disabilities face increased bullying victimization, including students with visible and invisible disabilities, students with physical, developmental, intellectual, emotional and sensory disabilities and others. A 2003 study found that 34% of students taking medication for ADHD reported bullying victimization at least 2-3 times a month, a substantial increase over the rate of bullying victimization from other students surveyed (Unnever and Cornell, 2003). Wiener and Mak (2009) also found high rates of victims among girls with Attention Deficit and Hyperactivity Disabilities. Langevin, Bortnick, Hammer and Wiebe's (1998) Canadian study examining the relationship between stuttering and selection as a target for bullying, found that at least 59% of students studied were bullied about their stuttering, 69% of students who stutter were also bullied about other things and that bullying very frequently takes place on at least a weekly basis.

Evidence suggests that the response of policymakers, educators and researchers to the bullying of students with disabilities has not been nearly sufficient to address the breadth or gravity of the problem. For example, Massachusetts Advocates for Children's (2009) survey of families of children on the autism spectrum found that almost 40% of said children experienced

bullying for in excess of a year and that while 92% of parents discussed the bullying with school officials, 68% of families found the response of the school district to be inadequate. Only 21.5% of parents surveyed heard about the bullying from the school, with 80.6% hearing from the student him or herself. Given that many students with disabilities face significant communication barriers and are thus unable to report bullying and victimization themselves, protecting the rights of parents to be informed when their children face incidents of bullying or victimization may be a critical area for future law and practice around bullying. Increased research in this area is also necessary. While the existing literature has clearly established that students with disabilities face higher rates of bullying and victimization than the general student population, very little research on bullying prevention has focused on students with disabilities either in isolation or as an identified sub-category in broader bullying prevention initiatives.

Who Qualifies as a Student with a Disability?

One of the first and most important legal questions with respect to bullying and students with disabilities is: who qualifies as a student with a disability? The answer to this question varies depending on the law under question. There are two major definitions of disability that are relevant in the educational context: students with disabilities under Section 504 of the Rehabilitation Act and students with disabilities under IDEA. To be a student with a disability under Section 504, a student must, (1) have a physical or mental impairment that substantially limits one or more major life activities; (2) have a record of such an impairment; or (3) be regarded as having such an impairment (ED, 2010).” While there does not exist a comprehensive list of what constitutes a physical or mental impairment, the term is intended to be construed broadly. Recently, in the ADA Amendments Act of 2008, Congress provided a non-exhaustive list of major life activities, including but not limited to, “caring for oneself, performing manual tasks, seeing, hearing, eating, sleeping, walking, standing, lifting, bending, speaking, breathing, learning, reading, concentrating, thinking, communicating, and working (ADA, 2008). The ADA Amendments Act makes clear that the ADA’s, and as a result Section 504’s, definition of disability is intended to be construed very broadly. IDEA’s definition of a child with a disability is narrower, in part because of the broader legal rights and educational entitlements available to eligible students under IDEA. Under IDEA, a child with a disability must be evaluated and determined to fall within one of a series of specific, defined disability categories, such as intellectual disability, deafness, blindness, emotional disturbance, autism, specific learning disability and others, and need special education and related services by reason thereof (ADA, 2008).

Bullying and Existing Disability and Special Education Laws

Bullying prevention efforts interact in various ways with disability nondiscrimination laws, some of which are similar to dynamics around laws protecting other minority groups while others remain unique. In 2000, the Department of Education’s Office of Special Education and Rehabilitative Services (OSERS) and Office on Civil Rights (OCR) issued a joint, “Dear Colleague” letter highlighting the issue of disability harassment, a category within which bullying of students with disabilities is included (ED, 2000). The letter noted that several laws

were relevant to the issue of disability harassment. It notes that educational institutions, including both K-12 schools and institutions of higher education, have a responsibility to ensure equal educational opportunity for all students and that disability harassment denies that right and as a result is a form of discrimination prohibited by Section 504 of the Rehabilitation Act and Title II of the Americans with Disabilities Act. The ED (2000) letter defines disability harassment as “intimidation or abusive behavior toward a student based on disability that creates a hostile environment by interfering with or denying a student’s participation in or receipt of benefits, services, or opportunities in the institution’s program. .When harassing conduct is sufficiently severe, persistent, or pervasive that it creates a hostile environment, it can violate a student’s rights under the Section 504 and Title II regulations. .even if there are no tangible effects on the student (ED, 2000, p. 3).” The letter also notes that failure to address disability harassment may constitute a violation of the Individuals with Disabilities Education Act’s (IDEA) guarantee of a Free and Appropriate Public Education (FAPE) for students with disabilities when harassment prevents or diminishes the ability of a student to benefit from his or her education (ED, 2000. p.4). Although the letter does not say so specifically, bullying of students with disabilities may also constitute a violation of IDEA when it forces a student with a disability into a more restrictive educational setting such as a self-contained classroom or out of district placement in order to benefit from their educational experience, given IDEA’s legal right for students with disabilities to receive a Free and Appropriate Public Education (FAPE) in the Least Restrictive Environment (LRE).

More recently, the ED’s (2010) “Dear Colleague” letter included disability in a list of protected classes (e.g., race, gender, disability). Schools must respond to bullying and harassment perpetrated on the basis of membership in these protected classes. The ED (2010) letter spelled out the legal obligations schools possess under existing civil rights laws, including Section 504 of the Rehabilitation Act and Title II of the Americans with Disabilities Act and provided examples of various types of harassment and bullying against protected classes as well as potential school responses. Among the responses mentioned in the context of disability include “disciplinary action against the harassers, consultation with the district’s Section 504/Title II coordinator to ensure a comprehensive and effective response, special training for staff on recognizing and effectively responding to harassment of students with disabilities, and monitoring to ensure that the harassment did not resume (ED, 2010).”

It should be noted that while ED 2010 speaks primarily of harassment on the basis of protected class status, IDEA’s FAPE and LRE provisions may impose upon school districts a legal responsibility to act to protect students with disabilities eligible under IDEA from more general bullying and harassment as well. IDEA does not simply require districts to protect students with disabilities from bullying, harassment and overt discrimination on the basis of disability, but also creates an entitlement to a “free and appropriate public education in the least restrictive environment” which frequently requires funding related services, making educational accommodations and modifications as well as working to address issues such as school climate, access needs and other factors that might hinder a student’s ability to fully benefit from their education in the least restrictive environment possible. For example, when bullying of a student with a disability results in a student being transferred into a self-contained classroom or a special education school serving only students with disabilities as opposed to receiving an education in a general classroom setting, a student’s IDEA LRE rights may have been violated regardless of the type of bullying that precipitated the change in placement and regardless of whether parents or guardians “chose” the segregated setting as a result of fear of

bullying or other forms of intimidation or duress. As research shows that students with disabilities are not only subject to bullying and harassment on the basis of disability, but also are frequently more vulnerable to bullying and harassment of a more general nature as well, it is important that the potentially broader protections of IDEA are in place for this population.

IDEA is relevant to the issue of bullying of students with disabilities in at least two additional respects. First, the Individualized Education Plan process represents a potentially useful avenue to address bullying through both pro-active and reactive measures. Under IDEA, students with disabilities receive an Individualized Education Plan (IEP) as a result of a deliberative process involving educators, administrators, child study team members, parents and, where appropriate, the student. The IEP outlines the student's educational plan, accommodations, related services and goals for the year. The IEP can be useful both for helping students develop useful self-advocacy skills to avoid or effectively respond to bullying and harassment from peers or adults. It can also be a useful way of planning for how educators can intervene in the classroom, during extracurricular activities or in other school settings to help protect students from bullying behaviors. The utility of the IEP as a tool to address bullying has been recognized at the state level. Massachusetts (2010) recently passed into law a requirement that IEPs "address the skills and proficiencies needed to avoid and respond to bullying, harassment or teasing" for students with social skills related disabilities and whenever a student with a disability is vulnerable to disability-based bullying, harassment or teasing.

Secondly, IDEA's provisions around discipline state that a student with a disability may not have their educational placement changed in response to behavior that was a manifestation of a student's disability or the result of a school's failure to implement the student's IEP (34 C.F.R. § 300.530). In an instance in which a child with a disability under IDEA is engaged in bullying behavior, it is important that anti-bullying measures not come into conflict with or serve to restrict existing rights under IDEA. State anti-bullying laws have in many instances attempted to address this with language indicating that anti-bullying laws are not intended to infringe upon IDEA rights. Such language must be carefully constructed to ensure that it does not serve to exclude students with disabilities from anti-bullying efforts and protections. For example, an early proposed draft of a New Jersey (2010) anti-bullying law had attempted to address the potential conflict with IDEA by excluding bullying and harassment which occurred "exclusively among or between special education students or students with developmental disabilities". Such an approach would have deprived students with disabilities of the same civil rights protections other groups would benefit from in the anti-bullying legislation. Instead, the legislation was modified before it passed the legislature to simply clarify that, "nothing contained in the "Anti-Bullying Bill of Rights Act," shall alter or reduce the rights of a student with a disability with regard to disciplinary actions or to general or special educational services and supports."

Policy Recommendations

Effectively addressing bullying of students with disabilities will require undertaking action as part of both general and special education policy. Students with disabilities must be included on an equal basis with other protected classes in bullying prevention efforts undertaken as part of general education laws and policy initiatives such as the upcoming re-authorization of the Elementary and Secondary Education Act and bullying prevention efforts from the Health

Resources and Services Administration (HRSA) and the Department of Education Office for Civil Rights. In addition, it is also necessary to strengthen and increase the use of anti-bullying tools unique to students with disabilities, such as IEP process and IDEA's guarantee of a Free and Appropriate Public Education (FAPE) in the Least Restrictive Environment (LRE). We recommend the following policy actions:

Recommendations for School and Classroom Level Change

1. **Requiring Parental Notification:** Families frequently learn of incidents of bullying and harassment only well after they occur, if at all. As Congress considers means by which to incorporate bullying prevention into the re-authorization of the Elementary and Secondary Education Act (ESEA) and other relevant education policy laws, a requirement that parents be notified when their child is involved as either victim or perpetrator in an incident of bullying or harassment may be worth consideration. This may be particularly important for students with communication related disabilities whose families may not otherwise become aware of incidents. However, part of the nature of bullying is that the victim may blame themselves or be too ashamed to report what happened, so reporting requirements should not be limited to students with disabilities.
2. **Expanding the Role of the IEP:** For students with disabilities, the IEP is a natural tool for bullying prevention and elimination. The ED Office on Special Education and Rehabilitation Services should expand technical assistance on how to use the IEP to protect students with disabilities from bullying and harassment and effective ways to address bullying behaviors that may be linked to a disability. Federal support to positive behavior interventions and supports should be broad enough to address bullying. Consideration should be given to incorporating bullying prevention as a priority within the IEP in the next re-authorization of the Individuals with Disabilities Education Act (IDEA).
3. **Meaningful Accountability:** Merely prohibiting certain types of behavior and requiring training will not necessarily suffice to solve the bullying problem. Families must have a continuum of meaningful and effective enforcement options to protect their children. Federal agencies and Congress should consider a range of possible enforcement measures, including potentially a private right of action aimed at holding schools accountable for severe, persistent and pervasive bullying and harassment.

Recommendations across the Lifespan

4. **Eliminating Workplace Bullying:** Bullying is not limited to educational settings. Many youth and adults continue to face bullying, harassment and other forms of victimization during transition and within the workplace. The Employment Equal Opportunity Commission (EEOC) should be recognized and invited as a critical stakeholder in federal bullying prevention efforts and issues surrounding workplace bullying should be incorporated into our evolving national conversation on bullying. The Department of Labor should develop an infrastructure to address workplace

bullying through measures to facilitate public education, technical assistance and enforcement.

5. **Fighting Hate Crimes:** The Department of Justice and the Federal Bureau of Investigation should work collaboratively with civil rights and community groups, including those in the disability community, to ensure effective and comprehensive implementation and enforcement of the Matthew Shepard and James Byrd, Jr. Hate Crimes Prevention Act for both adults and youth.

Recommendations at the Federal Level

6. **Collaborating in Federal Research Program on Bullying Prevention:** Given that bullying prevention has implications for educational practice, civil rights and public health, research will play a crucial role in shaping anti-bullying efforts in the coming years. The executive branch should ensure that disability is included in federal research efforts on bullying through encouraging the involvement of disability-oriented agencies with mandated broad research and policy missions, like the National Institute for Disability and Rehabilitation Research (NIDRR) and the National Council on Disability (NCD), and in broader federal bullying prevention efforts such as the Federal Partners in Bullying Prevention Task Force.
7. **Technical Assistance:** The Department of Education should develop and implement, in collaboration with disability and other civil rights communities, an infrastructure for technical assistance to State and Local Education Authorities on bullying prevention to facilitate effective research to practice.
8. **Professional Development:** The Department of Education should place bullying prevention as a priority in existing personnel development grants for both general and special education. Congress should consider bullying prevention and reduction as a personnel preparation and development priority in the Elementary and Secondary Education Act (ESEA).
9. **Broadening Data Collection:** Disability must be included in all federal data collection around bullying, victimization, violence, harassment, and hate crimes.

DEAR COLLEAGUE LETTER: BULLYING AND HARASSMENT

UNITED STATES DEPARTMENT OF EDUCATION OFFICE FOR CIVIL RIGHTS

October 26, 2010

Dear Colleague:

In recent years, many state departments of education and local school districts have taken steps to reduce bullying in schools. The U.S. Department of Education (Department) fully supports these efforts. Bullying fosters a climate of fear and disrespect that can seriously impair the physical and psychological health of its victims and create conditions that negatively affect learning, thereby undermining the ability of students to achieve their full potential. The movement to adopt anti-bullying policies reflects schools' appreciation of their important responsibility to maintain a safe learning environment for all students. I am writing to remind you, however, that some student misconduct that falls under a school's anti-bullying policy also may trigger responsibilities under one or more of the federal antidiscrimination laws enforced by the Department's Office for Civil Rights (OCR). As discussed in more detail below, by

limiting its response to a specific application of its anti-bullying disciplinary policy, a school may fail to properly consider whether the student misconduct also results in discriminatory harassment.

The statutes that OCR enforces include Title VI of the Civil Rights Act of 1964¹ (Title VI), which prohibits discrimination on the basis of race, color, or national origin; Title IX of the Education Amendments of 1972² (Title IX), which prohibits discrimination on the basis of sex; Section 504 of the Rehabilitation Act of 1973³ (Section 504); and Title II of the Americans with Disabilities Act of 1990⁴ (Title II). Section 504 and Title II prohibit discrimination on the basis of disability.⁵ School districts may violate these civil rights statutes and the Department's implementing regulations when peer harassment based on race, color, national origin, sex, or disability is sufficiently serious that it creates a hostile environment and such harassment is encouraged, tolerated, not adequately addressed, or ignored by school employees.⁶ School personnel who understand their legal obligations to address harassment under these laws are in the best position to prevent it from occurring and to respond appropriately when it does. Although this letter focuses on the elementary and secondary school context, the legal principles also apply to postsecondary institutions covered by the laws and regulations enforced by OCR. Some school anti-bullying policies already may list classes or traits on which bases bullying or harassment is specifically prohibited. Indeed, many schools have adopted anti-bullying policies that go beyond prohibiting bullying on the basis of traits expressly protected by the federal civil rights laws enforced by OCR— race, color, national origin, sex, and disability—to include such bases as sexual orientation and religion. While this letter concerns your legal obligations under the laws enforced by OCR, other federal, state, and local laws impose additional obligations on schools.⁷ And, of course, even when bullying or harassment is not a civil rights violation, schools should still seek to prevent it in order to protect students from the physical and emotional harms that it may cause.

Harassing conduct may take many forms, including verbal acts and name-calling; graphic and written statements, which may include use of cell phones or the Internet; or other conduct that may be physically threatening, harmful, or humiliating. Harassment does not have to include intent to harm, be directed at a specific target, or involve repeated incidents. Harassment creates a hostile environment when the conduct is sufficiently severe, pervasive, or persistent so as to interfere with or limit a student's ability to participate in or benefit from the services, activities, or opportunities offered by a school. When such harassment is based on race, color, national origin, sex, or disability, it violates the civil rights laws that OCR enforces.⁸

A school is responsible for addressing harassment incidents about which it knows or reasonably⁹ should have known. In some situations, harassment may be in plain sight, widespread, or well-known to students and staff, such as harassment occurring in hallways, during academic or physical education classes, during extracurricular activities, at recess, on a school bus, or through graffiti in public areas. In these cases, the obvious signs of the harassment are sufficient to put the school on notice. In other situations, the school may become aware of misconduct, triggering an investigation that could lead to the discovery of additional incidents that, taken together, may constitute a hostile environment. In all cases, schools should have well-publicized policies prohibiting harassment and procedures for reporting and resolving¹⁰ complaints that will alert the school to incidents of harassment.

When responding to harassment, a school must take immediate and appropriate action to investigate or otherwise determine what occurred. The specific steps in a school's investigation will vary depending upon the nature of the allegations, the source of the complaint, the age of

the student or students involved, the size and administrative structure of the school, and other factors. In all cases, however, the inquiry should be prompt, thorough, and impartial.

If an investigation reveals that discriminatory harassment has occurred, a school must take prompt and effective steps reasonably calculated to end the harassment, eliminate any hostile environment and its effects, and prevent the harassment from recurring. These duties are a school's responsibility even if the misconduct also is covered by an anti-bullying policy, and regardless of whether a student has complained, asked the school to take action, or identified the harassment as a form of discrimination.

Appropriate steps to end harassment may include separating the accused harasser and the target, providing counseling for the target and/or harasser, or taking disciplinary action against the harasser. These steps should not penalize the student who was harassed. For example, any separation of the target from an alleged harasser should be designed to minimize the burden on the target's educational program (*e.g.*, not requiring the target to change his or her class schedule).

In addition, depending on the extent of the harassment, the school may need to provide training or other interventions not only for the perpetrators, but also for the larger school community, to ensure that all students, their families, and school staff can recognize harassment if it recurs and know how to respond.

A school also may be required to provide additional services to the student who was harassed in order to address the effects of the harassment, particularly if the school initially delays in responding or responds inappropriately or inadequately to information about harassment. An effective response also may need to include the issuance of new policies against harassment and new procedures by which students, parents, and employees may report allegations of harassment (or wide dissemination of existing policies and procedures), as well as wide distribution of the contact information for the district's Title IX and Section 504/Title II coordinators.¹¹

Finally, a school should take steps to stop further harassment and prevent any retaliation against the person who made the complaint (or was the subject of the harassment) or against those who provided information as witnesses. At a minimum, the school's responsibilities include making sure that the harassed students and their families know how to report any subsequent problems, conducting follow-up inquiries to see if there have been any new incidents or any instances of retaliation, and responding promptly and appropriately to address continuing or new problems.

When responding to incidents of misconduct, schools should keep in mind the following:

- The label used to describe an incident (*e.g.*, bullying, hazing, teasing) does not determine how a school is obligated to respond. Rather, the nature of the conduct itself must be assessed for civil rights implications. So, for example, if the abusive behavior is on the basis of race, color, national origin, sex, or disability, and creates a hostile environment, a school is obligated to respond in accordance with the applicable federal civil rights statutes and regulations enforced by OCR.
- When the behavior implicates the civil rights laws, school administrators should look beyond simply disciplining the perpetrators. While disciplining the perpetrators is likely a necessary step, it often is insufficient. A school's responsibility is to eliminate the hostile environment created by the harassment, address its effects, and take steps to ensure that harassment does not recur. Put differently, the unique effects of

discriminatory harassment may demand a different response than would other types of bullying.

Below, I provide hypothetical examples of how a school's failure to recognize student misconduct as discriminatory harassment violates students' civil rights.¹²

In each of the examples, the school was on notice of the harassment because either the school or a responsible employee knew or should have known of misconduct that constituted harassment. The examples describe how the school should have responded in each circumstance.

Title VI: Race, Color, or National Origin Harassment

Some students anonymously inserted offensive notes into African-American students' lockers and notebooks, used racial slurs, and threatened African-American students who tried to sit near them in the cafeteria. Some African-American students told school officials that they did not feel safe at school. The school investigated and responded to individual instances of misconduct by assigning detention to the few student perpetrators it could identify. However, racial tensions in the school continued to escalate to the point that several fights broke out between the school's racial groups.

In this example, school officials failed to acknowledge the pattern of harassment as indicative of a racially hostile environment in violation of Title VI. Misconduct need not be directed at a particular student to constitute discriminatory harassment and foster a racially hostile environment. Here, the harassing conduct included overtly racist behavior (e.g., racial slurs) and also targeted students on the basis of their race (e.g., notes directed at African-American students). The nature of the harassment, the number of incidents, and the students' safety concerns demonstrate that there was a racially hostile environment that interfered with the students' ability to participate in the school's education programs and activities.

Had the school recognized that a racially hostile environment had been created, it would have realized that it needed to do more than just discipline the few individuals whom it could identify as having been involved. By failing to acknowledge the racially hostile environment, the school failed to meet its obligation to implement a more systemic response to address the unique effect that the misconduct had on the school climate. A more effective response would have included, in addition to punishing the perpetrators, such steps as reaffirming the school's policy against discrimination (including racial harassment), publicizing the means to report allegations of racial harassment, training faculty on constructive responses to racial conflict, hosting class discussions about racial harassment and sensitivity to students of other races, and conducting outreach to involve parents and students in an effort to identify problems and improve the school climate. Finally, had school officials responded appropriately and aggressively to the racial harassment when they first became aware of it, the school might have prevented the escalation of violence that occurred.¹³

- Over the course of a school year, school employees at a junior high school received reports of several incidents of anti-Semitic conduct at the school. Anti-Semitic graffiti, including swastikas, was scrawled on the stalls of the school bathroom. When

custodians discovered the graffiti and reported it to school administrators, the administrators ordered the graffiti removed but took no further action. At the same school, a teacher caught two ninth-graders trying to force two seventh-graders to give them money. The ninth-graders told the seventh-graders, “You Jews have all of the money, give us some.” When school administrators investigated the incident, they determined that the seventh-graders were not actually Jewish. The school suspended the perpetrators for a week because of the serious nature of their misconduct. After that incident, younger Jewish students started avoiding the school library and computer lab because they were located in the corridor housing the lockers of the ninth-graders. At the same school, a group of eighth-grade students repeatedly called a Jewish student “Drew the dirty Jew.” The responsible eighth-graders were reprimanded for teasing the Jewish student.

The school administrators failed to recognize that anti-Semitic harassment can trigger responsibilities under Title VI. While Title VI does not cover discrimination based solely on religion,¹⁴ groups that face discrimination on the basis of actual or perceived shared ancestry or ethnic characteristics may not be denied protection under Title VI on the ground that they also share a common faith. These principles apply not just to Jewish students, but also to students from any discrete religious group that shares, or is perceived to share, ancestry or ethnic characteristics (e.g., Muslims or Sikhs). Thus, harassment against students who are members of any religious group triggers a school’s Title VI responsibilities when the harassment is based on the group’s actual or perceived shared ancestry or ethnic characteristics, rather than solely on its members’ religious practices. A school also has responsibilities under Title VI when its students are harassed based on their actual or perceived citizenship or residency in a country whose residents share a dominant religion or a distinct religious identity.¹⁵

In this example, school administrators should have recognized that the harassment was based on the students’ actual or perceived shared ancestry or ethnic identity as Jews (rather than on the students’ religious practices). The school was not relieved of its responsibilities under Title VI because the targets of one of the incidents were not actually Jewish. The harassment was still based on the perceived ancestry or ethnic characteristics of the targeted students. Furthermore, the harassment negatively affected the ability and willingness of Jewish students to participate fully in the school’s education programs and activities (e.g., by causing some Jewish students to avoid the library and computer lab). Therefore, although the discipline that the school imposed on the perpetrators was an important part of the school’s response, discipline alone was likely insufficient to remedy a hostile environment. Similarly, removing the graffiti, while a necessary and important step, did not fully satisfy the school’s responsibilities. As discussed above, misconduct that is not directed at a particular student, like the graffiti in the bathroom, can still constitute discriminatory harassment and foster a hostile environment. Finally, the fact that school officials considered one of the incidents “teasing” is irrelevant for determining whether it contributed to a hostile environment.

Because the school failed to recognize that the incidents created a hostile environment, it addressed each only in isolation, and therefore failed to take prompt and effective steps reasonably calculated to end the harassment and prevent its recurrence. In addition to disciplining the perpetrators, remedial steps could have included counseling the perpetrators about the hurtful effect of their conduct, publicly labeling the incidents as anti-Semitic, reaffirming the school’s policy against discrimination, and publicizing the means by which students may report harassment. Providing teachers with training to recognize and address anti-Semitic incidents also would have increased the effectiveness of the school’s response. The school could also have created an age-appropriate program to

educate its students about the history and dangers of anti-Semitism, and could have conducted outreach to involve parents and community groups in preventing future anti-Semitic harassment.

Title IX: Sexual Harassment

Shortly after enrolling at a new high school, a female student had a brief romance with another student. After the couple broke up, other male and female students began routinely calling the new student sexually charged names, spreading rumors about her sexual behavior, and sending her threatening text messages and e-mails. One of the student's teachers and an athletic coach witnessed the name calling and heard the rumors, but identified it as "hazing" that new students often experience. They also noticed the new student's anxiety and declining class participation. The school attempted to resolve the situation by requiring the student to work the problem out directly with her harassers.

Sexual harassment is unwelcome conduct of a sexual nature, which can include unwelcome sexual advances, requests for sexual favors, or other verbal, nonverbal, or physical conduct of a sexual nature. Thus, sexual harassment prohibited by Title IX can include conduct such as touching of a sexual nature; making sexual comments, jokes, or gestures; writing graffiti or displaying or distributing sexually explicit drawings, pictures, or written materials; calling students sexually charged names; spreading sexual rumors; rating students on sexual activity or performance; or circulating, showing, or creating e-mails or Web sites of a sexual nature.

In this example, the school employees failed to recognize that the "hazing" constituted sexual harassment. The school did not comply with its Title IX obligations when it failed to investigate or remedy the sexual harassment. The conduct was clearly unwelcome, sexual (*e.g.*, sexual rumors and name calling), and sufficiently serious that it limited the student's ability to participate in and benefit from the school's education program (*e.g.*, anxiety and declining class participation).

The school should have trained its employees on the type of misconduct that constitutes sexual harassment. The school also should have made clear to its employees that they could not require the student to confront her harassers. Schools may use informal mechanisms for addressing harassment, but only if the parties agree to do so on a voluntary basis. Had the school addressed the harassment consistent with Title IX, the school would have, for example, conducted a thorough investigation and taken interim measures to separate the student from the accused harassers. An effective response also might have included training students and employees on the school's policies related to harassment, instituting new procedures by which employees should report allegations of harassment, and more widely distributing the contact information for the district's Title IX coordinator. The school also might have offered the targeted student tutoring, other academic assistance, or counseling as necessary to remedy the effects of the harassment.¹⁶

Title IX: Gender-Based Harassment

Over the course of a school year, a gay high school student was called names (including anti-gay slurs and sexual comments) both to his face and on social networking sites, physically assaulted, threatened, and ridiculed because he did not conform to stereotypical notions of how

teenage boys are expected to act and appear (e.g., effeminate mannerisms, nontraditional choice of extracurricular activities, apparel, and personal grooming choices). As a result, the student dropped out of the drama club to avoid further harassment. Based on the student's self-identification as gay and the homophobic nature of some of the harassment, the school did not recognize that the misconduct included discrimination covered by Title IX. The school responded to complaints from the student by reprimanding the perpetrators consistent with its anti-bullying policy. The reprimands of the identified perpetrators stopped the harassment by those individuals. It did not, however, stop others from undertaking similar harassment of the student.

As noted in the example, the school failed to recognize the pattern of misconduct as a form of sex discrimination under Title IX. Title IX prohibits harassment of both male and female students regardless of the sex of the harasser—*i.e.*, even if the harasser and target are members of the same sex. It also prohibits gender-based harassment, which may include acts of verbal, nonverbal, or physical aggression, intimidation, or hostility based on sex or sex-stereotyping. Thus, it can be sex discrimination if students are harassed either for exhibiting what is perceived as a stereotypical characteristic for their sex, or for failing to conform to stereotypical notions of masculinity and femininity. Title IX also prohibits sexual harassment and gender-based harassment of all students, regardless of the actual or perceived sexual orientation or gender identity of the harasser or target.

Although Title IX does not prohibit discrimination based solely on sexual orientation, Title IX does protect all students, including lesbian, gay, bisexual, and transgender (LGBT) students, from sex discrimination. When students are subjected to harassment on the basis of their LGBT status, they may also, as this example illustrates, be subjected to forms of sex discrimination prohibited under Title IX. The fact that the harassment includes anti-LGBT comments or is partly based on the target's actual or perceived sexual orientation does not relieve a school of its obligation under Title IX to investigate and remedy overlapping sexual harassment or gender-based harassment. In this example, the harassing conduct was based in part on the student's failure to act as some of his peers believed a boy should act. The harassment created a hostile environment that limited the student's ability to participate in the school's education program (*e.g.*, access to the drama club). Finally, even though the student did not identify the harassment as sex discrimination, the school should have recognized that the student had been subjected to gender-based harassment covered by Title IX.

In this example, the school had an obligation to take immediate and effective action to eliminate the hostile environment. By responding to individual incidents of misconduct on an *ad hoc* basis only, the school failed to confront and prevent a hostile environment from continuing. Had the school recognized the conduct as a form of sex discrimination, it could have employed the full range of sanctions (including progressive discipline) and remedies designed to eliminate the hostile environment. For example, this approach would have included a more comprehensive response to the situation that involved notice to the student's teachers so that they could ensure the student was not subjected to any further harassment, more aggressive monitoring by staff of the places where harassment occurred, increased training on the scope of the school's harassment and discrimination policies, notice to the target and harassers of available counseling services and resources, and educating the entire school community on civil rights and expectations of tolerance, specifically as they apply to gender stereotypes. The school also should have taken steps to clearly communicate the message that the school does not tolerate harassment and will be responsive to any information about such conduct.¹⁷

Section 504 and Title II: Disability Harassment

Several classmates repeatedly called a student with a learning disability “stupid,” “idiot,” and “retard” while in school and on the school bus. On one occasion, these students tackled him, hit him with a school binder, and threw his personal items into the garbage. The student complained to his teachers and guidance counselor that he was continually being taunted and teased. School officials offered him counseling services and a psychiatric evaluation, but did not discipline the offending students. As a result, the harassment continued. The student, who had been performing well academically, became angry, frustrated, and depressed, and often refused to go to school to avoid the harassment.

In this example, the school failed to recognize the misconduct as disability harassment under Section 504 and Title II. The harassing conduct included behavior based on the student’s disability, and limited the student’s ability to benefit fully from the school’s education program (e.g., absenteeism). In failing to investigate and remedy the misconduct, the school did not comply with its obligations under Section 504 and Title II.

Counseling may be a helpful component of a remedy for harassment. In this example, however, since the school failed to recognize the behavior as disability harassment, the school did not adopt a comprehensive approach to eliminating the hostile environment. Such steps should have at least included disciplinary action against the harassers, consultation with the district’s Section 504/Title II coordinator to ensure a comprehensive and effective response, special training for staff on recognizing and effectively responding to harassment of students with disabilities, and monitoring to ensure that the harassment did not resume.¹⁸

I encourage you to reevaluate the policies and practices your school uses to address bullying¹⁹ and harassment to ensure that they comply with the mandates of the federal civil rights laws. For your convenience, the following is a list of online resources that further discuss the obligations of districts to respond to harassment prohibited under the federal antidiscrimination laws enforced by OCR:

- *Sexual Harassment: It’s Not Academic* (Revised 2008): <http://www.ed.gov/about/offices/list/ocr/docs/ocrshpam.html>
- *Dear Colleague Letter: Sexual Harassment Issues* (2006): <http://www2.ed.gov/about/offices/list/ocr/letters/sexhar-2006.html>
- *Dear Colleague Letter: Religious Discrimination* (2004): <http://www2.ed.gov/about/offices/list/ocr/religious-rights2004.html>
- *Dear Colleague Letter: First Amendment* (2003): <http://www.ed.gov/about/offices/list/ocr/firstamend.html>
- *Sexual Harassment Guidance* (Revised 2001): <http://www.ed.gov/about/offices/list/ocr/docs/shguide.html>
- *Dear Colleague Letter: Prohibited Disability Harassment* (2000): <http://www.ed.gov/about/offices/list/ocr/docs/disabharassltr.html>
- *Racial Incidents and Harassment Against Students* (1994): <http://www.ed.gov/about/offices/list/ocr/docs/race394.html>

Please also note that OCR has added new data items to be collected through its Civil Rights Data Collection (CRDC), which surveys school districts in a variety of areas related to civil rights in education. The CRDC now requires districts to collect and report information on allegations of harassment, policies regarding harassment, and discipline imposed for harassment. In 2009-10, the CRDC covered nearly 7,000 school districts, including all districts with more than 3,000 students. For more information about the CRDC data items, please visit <http://www2.ed.gov/about/offices/list/ocr/whatsnew.html>.

OCR is committed to working with schools, students, students' families, community and advocacy organizations, and other interested parties to ensure that students are not subjected to harassment. Please do not hesitate to contact OCR if we can provide assistance in your efforts to address harassment or if you have other civil rights concerns.

For the OCR regional office serving your state, please visit:

<http://wdcrobcolp01.ed.gov/CFAPPS/OCR/contactus.cfm>, or call OCR's Customer Service Team at 1-800-421-3481.

I look forward to continuing our work together to ensure equal access to education, and to promote safe and respectful school climates for America's students.

Sincerely,

/s/

Russlynn Ali

Assistant Secretary for Civil Rights

SECRETARY OF EDUCATION BULLYING LAW AND POLICY MEMO

UNITED STATES DEPARTMENT OF EDUCATION OFFICE OF THE SECRETARY

December 16, 2010

Dear Colleagues:

Recent incidents of bullying have demonstrated its potentially devastating effects on students, schools, and communities and have spurred a sense of urgency among State and local educators and policymakers to take action to combat bullying. The U.S. Department of Education (Department) shares this sense of urgency and is taking steps to help school officials effectively reduce bullying in our Nation's schools. Bullying can be extremely damaging to students, can disrupt an environment conducive to learning, and should not be tolerated in our schools.

Along with our partners from the Departments of Health and Human Services, Agriculture, Interior, Defense, and Justice, we are in the process of developing key strategies to support and encourage efforts to prevent bullying in our schools. Our ongoing work has included the first-ever Federal Bullying Prevention Summit in August, the launch of our interagency bullying-resource Web site, <http://www.bullyinginfo.org>, the continued support and growth of the Stop Bullying Now! campaign, and the development of research and guidance on bullying

prevention. The Department also awarded eleven Safe and Supportive Schools Grants to states to develop measurement systems to assess schools' conditions for learning, including the prevalence of bullying, and to implement programs to improve overall school safety.

Recent guidance includes a Dear Colleague Letter issued on October 26 by the Department's Office for Civil Rights (OCR) that explains how, under certain circumstances, bullying may trigger legal responsibilities for schools under the civil rights laws enforced by OCR and the Department of Justice that prohibit discrimination and harassment based on race, color, national origin, sex, disability, and religion.²⁰ Schools must protect students from bullying and harassment on these bases, in addition to any obligations under state and local law.

Numerous stakeholders, including the National Conference of State Legislatures, the National Association of School Boards, the Leadership Conference on Civil and Human Rights, individual State legislators, and local school districts, among others, have asked the Department to provide assistance in crafting effective anti-bullying laws and policies. In response, the Department has prepared the attached summary of examples that illustrate how some states have tried to prevent and reduce bullying through legislation. States and local school districts can use these examples as technical assistance in drafting effective anti-bullying laws, regulations, and policies. The Department will also be working to produce additional helpful resource information.

Forty-five states have already passed laws addressing bullying or harassment in school. Ultimately State officials will determine whether new or revised legislation and policies should be introduced to update, improve, or add bullying prevention provisions. It is our hope that this information will be of assistance to State officials and other interested stakeholders.

Though laws are only a part of the cure for bullying, the adoption, publication, and enforcement of a clear and effective anti-bullying policy sends a message that all incidents of bullying must be addressed immediately and effectively, and that such behavior will not be tolerated. State laws, and their related district- and school-level policies, cannot work in isolation, however. When responding to bullying incidents, schools and districts should remember that maintenance of a safe and equitable learning environment for all students, including both victims and perpetrators of bullying, often requires a more comprehensive approach.

If you wish to receive further technical assistance on addressing bullying, please do not hesitate to contact the Department's Office of Safe and Drug-Free Schools by visiting its Web site at <http://www2.ed.gov/about/offices/list/osdfs/index.html> or by calling at 202-245-7896.

I look forward to continuing our work together to ensure equal access to education and to promote safe and respectful schools for all of our students.

Sincerely,

/s/

Arne Duncan

ANTI-BULLYING POLICIES: EXAMPLES OF PROVISIONS IN STATE LAWS

In response to requests for assistance by state and local officials, educators, and policymakers, we summarize below examples of key components of state anti-bullying laws. This document serves as technical assistance for those stakeholders looking to develop or revise anti-bullying legislation or policies. The Department has organized the key components into eleven categories for convenience. We include citations to state laws that illustrate the key components we identified, but we do not endorse any particular laws. Additional examples are included at the end of the document, but these citations are not intended to be comprehensive. Many other state and local laws and policies may provide helpful guidance on developing effective anti-bullying policies. As part of our technical assistance effort to disseminate useful information on this important topic, we welcome other examples of laws and policies that may be working effectively to address bullying in schools. States and local educational agencies (LEAs) should seek the guidance of state and local legal officials to ensure that the legislation is consistent with all applicable federal and state laws. The Department also plans to release a compendium of all current state laws and a study of their implementation.

The following are examples of components found in current state laws on bullying:

I. Purpose Statement

- Outlines the range of detrimental effects bullying has on students, including impacts on student learning, school safety, student engagement, and the school environment.
- Declares that any form, type, or level of bullying is unacceptable, and that every incident needs to be taken seriously by school administrators, school staff (including teachers), students, and students' families.
- *Example*^{ix}:
 - **Oklahoma:** Okla. Stat. Ann. Tit. 70, § 24-100.3 (2009): "The Legislature finds that bullying has a negative effect on the social environment of schools, creates a climate of fear among students, inhibits their ability to learn, and leads to other antisocial behavior. Bullying behavior has been linked to other forms of antisocial behavior, such as vandalism, shoplifting, skipping and dropping out of school, fighting, and the use of drugs and alcohol. . . . Successful programs to recognize, prevent, and effectively intervene in bullying behavior have been developed and replicated in schools across the country. These schools send the message that bullying behavior is not tolerated and, as a result, have improved safety and created a more inclusive learning environment."

II. Statement of Scope

- Covers conduct that occurs on the school campus, at school-sponsored activities or events (regardless of the location), on school-provided transportation, or through

school-owned technology or that otherwise creates a significant disruption to the school environment.

- *Example^x*:
 - **Indiana:** Ind. Code Ann. § 20-33-8-13.5 (b) (2010), Disciplinary Rule Requirements: “The discipline rules [related to bullying]...must apply when a student is: (1) on school grounds immediately before or during school hours, immediately after school hours, or at any other time when the school is being used by a school group; (2) off school grounds at a school activity, function, or event; (3) traveling to or from school or a school activity, function or event; or (4) using property or equipment provided by the school.”

III. Specification of Prohibited Conduct

- Provides a specific definition of bullying that includes a clear definition of cyberbullying. The definition of bullying includes a non-exclusive list of specific behaviors that constitute bullying, and specifies that bullying includes intentional efforts to harm one or more individuals, may be direct or indirect, is not limited to behaviors that cause physical harm, and may be verbal (including oral and written language) or non-verbal. The definition of bullying can be easily understood and interpreted by school boards, policymakers, school administrators, school staff, students, students’ families, and the community.
- Is consistent with other federal, state and local laws. (For guidance on school districts’ obligations to address bullying and harassment under federal civil rights laws, see the Dear Colleague Letter: Harassment and Bullying, issued by the Department’s Office for Civil Rights on October 26, 2010, available at <http://www2.ed.gov/about/offices/list/ocr/letters/colleague-201010.pdf>.)
- Prohibited Conduct also includes:
 1. Retaliation for asserting or alleging an act of bullying.
 2. Perpetuating bullying or harassing conduct by spreading hurtful or demeaning material even if the material was created by another person (e.g., forwarding offensive e-mails or text messages).
- *Examples^{xi,xii}*:
 - **Florida:** Fla. Stat. Ann. 1006.147(3) (2010): “(a) ‘Bullying’ means systematically and chronically inflicting physical hurt or psychological distress on one or more students and may involve: (1) Teasing; (2) Social exclusion; (3) Threat; (4) Intimidation; (5) Stalking; (6) Physical violence; (7) Theft; (8) Sexual, religious, or racial harassment; (9) Public humiliation; or (10) Destruction of property. . . . (d) The definitions of ‘bullying’ and ‘harassment’ include: (1) Retaliation against a student or school employee by another student or school employee for asserting or alleging an act of bullying or harassment...[and] (2) Perpetuation of [bullying or harassing] conduct ... by an individual or group with intent to demean, dehumanize, embarrass, or cause physical harm to a student. . . .”
 - **Kansas:** Kan. Stat. Ann. § 72-8256.C.2 (2009): “‘Cyberbullying’ means bullying by use of any electronic communication device through means including, but not

limited to, e-mail, instant messaging, text messages, blogs, mobile phones, pagers, online games and websites.”

IV. Enumeration of Specific Characteristics

- Explains that bullying may include, but is not limited to, acts based on actual or perceived characteristics of students who have historically been targets of bullying, and provides examples of such characteristics.
- Makes clear that bullying does not have to be based on any particular characteristic.
- *Examples*^{xiii} :
 - **North Carolina:** N.C. Gen. Stat. § 115C-407.15(a) (2010): “Bullying or harassing behavior includes, but is not limited to, acts reasonably perceived as being motivated by any actual or perceived differentiating characteristic, such as race, color, religion, ancestry, national origin, gender, socioeconomic status, academic status, gender identity, physical appearance, sexual orientation, or mental, physical, developmental, or sensory disability, or by association with a person who has or is perceived to have one or more of these characteristics.”
 - **Washington:** Wash. Rev. Code Ann. § 28A.300.285.2 (2010): “Nothing in this section requires the affected student to actually possess a characteristic that is a basis for the...bullying.”

V. Development and Implementation of LEA Policies

- Directs every LEA to develop and implement a policy prohibiting bullying, through a collaborative process with all interested stakeholders, including school administrators, staff, students, students’ families, and the community, in order to best address local conditions.
- *Example:*
 - **Maryland:** Md. Code Ann., Educ. § 7-424.1(c) (2010): “[1] Each county board shall establish a policy prohibiting bullying, harassment, or intimidation. . . . [3] A county board shall develop the policy in consultation with representatives of the following groups: (i) Parents or guardians of students; (ii) School employees and administrators; (iii) School volunteers; (iv) Students; and (v) Members of the community”^{xiv}

VI. Components of LEA Policies

A. Definitions

- Includes a definition of bullying consistent with the definitions specified in state law.
- *Example*^{xv} :
 - **Oregon:** Or. Rev. Stat. § 339.356.2 (2009): “School districts must include in the policy...(b) Definitions of “harassment,” “intimidation,” or “bullying,” and of “cyberbullying” that are consistent with [this statute].”

B. Reporting Bullying

- Includes a procedure for students, students' families, staff, and others to report incidents of bullying, including a process to submit such information anonymously and with protection from retaliation. The procedure identifies and provides contact information for the appropriate school personnel responsible for receiving the report and investigating the incident.
- *Example*^{xvi}:
 - **Georgia**: GA. Code Ann. § 20-2-751.4(c) (2010): "Such ... policy shall include: . . . (5) A procedure for a teacher or other school employee, student, parent, guardian, or other person who has control or charge of a student, either anonymously or in such person's name, at such person's option, to report or otherwise provide information on bullying activity; (6) A statement prohibiting retaliation following a report of bullying...."
- Requires that school personnel report, in a timely and responsive manner, incidents of bullying they witness or are aware of to a designated official.
- *Example*^{xvii}
 - **Wisconsin**: Wis. Stat. § 118.46.1(a) (2009): "The [policy on bullying] shall include all of the following: . . . (6) A requirement that school district officials and employees report incidents of bullying and identify the persons to whom the reports must be made."

C. Investigating and Responding to Bullying

- Includes a procedure for promptly investigating and responding to any report of an incident of bullying, including immediate intervention strategies for protecting the victim from additional bullying or retaliation, and includes notification to parents of the victim, or reported victim, of bullying and the parents of the alleged perpetrator, and, if appropriate, notification to law enforcement officials.^{xviii}
- *Example*^{xix}:
 - **Massachusetts**: 2010 Mass. Adv. Legis. Serv. Ch. No. 71.370(g) (2010): "...Upon receipt of such a report, the school principal or a designee shall promptly conduct an investigation. If the school principal or a designee determines that bullying or retaliation has occurred, the school principal or designee shall (i) notify the local law enforcement agency if the school principal or designee believes that criminal charges may be pursued against a perpetrator; (ii) take appropriate disciplinary action; (iii) notify the parents or guardians of a perpetrator; and (iv) notify the parents or guardians of the victim, and to the extent consistent with state and federal law, notify them of the action taken to prevent any further acts of bullying or retaliation."

D. Written Records

- Includes a procedure for maintaining written records of all incidents of bullying and their resolution.^{xx}
- *Example*^{xxi}:
 - **California**: Cal. Educ. Code § 234.1 (2010): "The department shall assess whether local educational agencies have done all of the following: . . . (e) Maintained

documentation of complaints and their resolution for a minimum of one review cycle.”

E. Sanctions

- Includes a detailed description of a graduated range of consequences and sanctions for bullying.^{xxii}
- *Example*^{xxiii}:
 - **Alabama:** Ala. Code § 16.28B.5 (2010): “The model policy, at a minimum, shall contain all of the following components: . . . [4] A series of graduated consequences for any student who commits an act of intimidation, harassment, violence or threats of violence. Punishment shall conform with applicable federal and state disability, antidiscrimination, and education laws and school discipline policies.”

F. Referrals

- Includes a procedure for referring the victim, perpetrator and others to counseling and mental and other health services, as appropriate.
- *Example*^{xxiv}:
 - **Maryland:** MD. Code. Ann., Educ. § 7-424.1.b (2010): “[2] The model policy...shall include: . . . (viii) Information about the types of support services available to the student bully, victim, and any bystanders....”

VII. Review of Local Policies

- Includes a provision for the state to review local policies on a regular basis to ensure the goals of the state statute are met.
- *Example*^{xxv} :
 - **Illinois:** 105 Ill. Comp. Stat. Ann. 5/27-23.7(d) (2010): “The policy must be updated every 2 years and filed with the State Board of Education after being updated. The State Board of Education shall monitor the implementation of policies created under [this subsection of the statute].”

VIII. Communication Plan

- Includes a plan for notifying students, students’ families, and staff of policies related to bullying, including the consequences for engaging in bullying.
- *Example*^{xxvi}:
 - **Arkansas:** Ark. Code Ann. § 6-18-514(b) (2009): “The policies shall: . . . [6] Require that notice of what constitutes bullying, that bullying is prohibited, and the consequences of engaging in bullying be conspicuously posted in every classroom, cafeteria, restroom, gymnasium, auditorium, and school bus in the district; and [7] Require that copies of the notice...be provided to parents, students, school volunteers, and employees.”

IX. Training and Preventive Education

- Includes a provision for school districts to provide training for all school staff, including, but not limited to, teachers, aides, support staff, and school bus drivers, on preventing, identifying, and responding to bullying.
- *Example*^{xxvii}:
 - **South Carolina**: S.C. Code Ann. § 59-63-140(E) (2009): “Information regarding a local school district policy against harassment, intimidation or bullying must be incorporated into a school employee training program. Training also should be provided to school volunteers who have significant contact with students.
 - **Massachusetts**: 2010 Mass. Adv. Legis. Serv. Ch. No. 92.3(d)-2010: “The plan...shall include a provision for ongoing professional development to build the skills of all staff members, including, but not limited to, educators, administrators, school nurses, cafeteria workers, custodians, bus drivers, athletic coaches, advisors to extracurricular activities and paraprofessionals, to prevent, identify and respond to bullying.”
- Encourages school districts to implement age-appropriate school- and community-wide bullying prevention programs.
- *Example*^{xxviii}:
 - **South Carolina**: S.C. Code Ann. § 59-63-140 (F) (2009): “Schools and school districts are encouraged to establish bullying prevention programs and other initiatives involving school staff, students, administrators, volunteers, parents, law enforcement, and community members.”

X. Transparency and Monitoring

- Includes a provision for LEAs to report annually to the state on the number of reported bullying incidents, and any responsive actions taken.
- *Example*^{xxix}
 - **New York**: N.Y. Educ. Law §15 (2010): “The Commissioner shall create a procedure under which material incidents of discrimination and harassment on school grounds or at a school function are reported to the department at least on an annual basis. Such procedure shall provide that such reports shall, wherever possible, also delineate the specific nature of such incidents. . . .”
- Includes a provision for LEAs to make data regarding bullying incidence publicly available in aggregate with appropriate privacy protections to ensure students are protected.^{xxx}
- *Examples*^{xxxi}:
 - **Iowa**: Iowa Code § 280.28.7 (2008): “The board of directors of a school district and the authorities in charge of each nonpublic school...shall report data collected...as specified by the department, to the local community.”
 - **Ohio**: Ohio Rev. Code Ann. § 3313.666.10 (2010): “...the district administration... [shall] provide ... a written summary of all reported incidents and post the summary on its web site....”

XI. Statement of Rights to Other Legal Recourse

- Includes a statement that the policy does not preclude victims from seeking other legal remedies.
- *Example:*
 - **Oregon:** Or. Rev. Stat. Ann. § 339.364 (2009): “Victim may seek redress under other laws. ...[This statute] may not be interpreted to prevent a victim of harassment, intimidation or bullying or a victim of cyberbullying from seeking redress under any other available law, whether civil or criminal.”

End Notes

ⁱ Education support professionals include paraprofessionals, maintenance staff, clerical staff, school transportation staff, cafeteria staff, security staff, health staff, technical staff, and other non-teaching support staff.

ⁱⁱ In the mid-1990s, the NEA membership mandated that the Association create a training program for its members on student-to-student sexual harassment and bullying. The NEA developed and constantly updated training curricula on these topics and has continued to conduct such training since that time.

ⁱⁱⁱ The research-based NEA Bullying Survey was developed by a team of experts in this field from John Hopkins University (Bradshaw, Waasdorp, & O’Brennan, 2010a). Bullying was defined on the survey as “...*intentional and repeated aggressive acts that can be physical – such as hitting – verbal – such as threats, or name calling – or relational, such as spreading rumors, or influencing social relationships. Bullying typically occurs in situations where there is a power or status difference.*” The data were collected from a nationally representative sample of 5,064 NEA members, including 2,163 teachers and 2,901 ESPs, in April 2010 using web- and phone-based surveys. The sample was designed to allow for comparisons across grade level and job category, with particular emphasis on ESPs, who have been largely overlooked in previous research on bullying (Bradshaw, Waasdorp, & O’Brennan, 2010b). The weighted sample reflects the NEA population, with 82% professional staff (teachers 85%, special educators 4%, remedial/ESL 2%, librarians 2%, counselors 3%, and other 4%) and 18% ESPs (paraprofessionals 49%, maintenance 14%, clerical 10%, bus drivers 10%, cafeteria workers 7%, security 1%, health 2%, technical 2%, and other 6%). Women represented 80% of the sample and 89% self-identified as White (Black 5%, Hispanic 4%, and others 2%). The sample included staff employed in a variety of school locations (suburban 34%, small town 24%, urban 24%, and rural areas 18%). Approximately 39% worked with students in elementary, 19% middle, and 27% high schools, with the remaining 16% working across multiple grade levels. Certain variables were statistically adjusted for in the analyses (i.e., school level, school location, web vs. phone survey modality, and amount of time spent with students), as they may have influenced participants’ responses to survey questions.

End Notes for Dear Colleague Letter: Bullying and Harassment; Secretary of Education Bullying Law and Policy Memo

¹ 42 U.S.C. § 2000d *et seq.*

² 20 U.S.C. § 1681 *et seq.*

³ 29 U.S.C. § 794.

⁴ 42 U.S.C. § 12131 *et seq.*

⁵ OCR also enforces the Age Discrimination Act of 1975, 42 U.S.C. § 6101 *et seq.*, and the Boy Scouts of America Equal Access Act, 20 U.S.C. § 7905. This letter does not specifically address those statutes.

⁶ The Department's regulations implementing these statutes are in 34 C.F.R. parts 100, 104, and 106. Under these federal civil rights laws and regulations, students are protected from harassment by school employees, other students, and third parties. This guidance focuses on peer harassment, and articulates the legal standards that apply in administrative enforcement and in court cases where plaintiffs are seeking injunctive relief.

⁷ For instance, the U.S. Department of Justice (DOJ) has jurisdiction over Title IV of the Civil Rights Act of 1964, 42 U.S.C. § 2000c (Title IV), which prohibits discrimination on the basis of race, color, sex, religion, or national origin by public elementary and secondary schools and public institutions of higher learning. State laws also provide additional civil rights protections, so districts should review these statutes to determine what protections they afford (*e.g.*, some state laws specifically prohibit discrimination on the basis of sexual orientation).

⁸ Some conduct alleged to be harassment may implicate the First Amendment rights to free speech or expression. For more information on the First Amendment's application to harassment, see the discussions in OCR's Dear Colleague Letter: First Amendment (July 28, 2003), available at <http://www.ed.gov/about/offices/list/ocr/firstamend.html>, and OCR's *Revised Sexual Harassment Guidance: Harassment of Students by School Employees, Other Students, or Third Parties* (Jan. 19, 2001) (*Sexual Harassment Guidance*), available at <http://www.ed.gov/about/offices/list/ocr/docs/shguide.html>.

⁹ A school has notice of harassment if a responsible employee knew, or in the exercise of reasonable care should have known, about the harassment. For a discussion of what a "responsible employee" is, see OCR's *Sexual Harassment Guidance*.

¹⁰ Districts must adopt and publish grievance procedures providing for prompt and equitable resolution of student and employee sex and disability discrimination complaints, and must notify students, parents, employees, applicants, and other interested parties that the district does not discriminate on the basis of sex or disability. See 28 C.F.R. § 35.106; 28 C.F.R. § 35.107(b); 34 C.F.R. § 104.7(b); 34 C.F.R. § 104.8; 34 C.F.R. § 106.8(b); 34 C.F.R. § 106.9.

¹¹ Districts must designate persons responsible for coordinating compliance with Title IX, Section 504, and Title II, including the investigation of any complaints of sexual, gender-based, or disability harassment. See 28 C.F.R. § 35.107(a); 34 C.F.R. § 104.7(a); 34 C.F.R. § 106.8(a).

¹² Each of these hypothetical examples contains elements taken from actual cases.

¹³ More information about the applicable legal standards and OCR's approach to investigating allegations of harassment on the basis of race, color, or national origin is included in *Racial Incidents and Harassment Against Students at Educational Institutions: Investigative Guidance*, 59 Fed. Reg. 11,448 (Mar. 10, 1994), available at <http://www.ed.gov/about/offices/list/ocr/docs/race394.html>.

¹⁴ As noted in footnote seven, DOJ has the authority to remedy discrimination based solely on religion under Title IV.

¹⁵ More information about the applicable legal standards and OCR's approach to investigating complaints of discrimination against members of religious groups is included in OCR's Dear Colleague Letter: Title VI and Title IX Religious Discrimination in Schools and Colleges (Sept. 13, 2004), available at <http://www2.ed.gov/about/offices/list/ocr/religious-rights2004.html>.

¹⁶ More information about the applicable legal standards and OCR's approach to investigating allegations of sexual harassment is included in OCR's *Sexual Harassment Guidance*, available at <http://www.ed.gov/about/offices/list/ocr/docs/shguide.html>.

¹⁷ Guidance on gender-based harassment is also included in OCR's *Sexual Harassment Guidance*, available at <http://www.ed.gov/about/offices/list/ocr/docs/shguide.html>.

¹⁸ More information about the applicable legal standards and OCR's approach to investigating allegations of disability harassment is included in OCR's Dear Colleague Letter: Prohibited Disability Harassment (July 25, 2000), available at <http://www2.ed.gov/about/offices/list/ocr/docs/disabharassltr.html>.

¹⁹ For resources on preventing and addressing bullying, please visit <http://www.bullyinginfo.org>, a Web site established by a federal Interagency Working Group on Youth Programs. For information on the Department's bullying prevention resources, please visit the Office of Safe and Drug-Free Schools' Web site at

<http://www.ed.gov/offices/OESE/SDFS>. For information on regional Equity Assistance Centers that assist schools in developing and implementing policies and practices to address issues regarding race, sex, or national origin discrimination, please visit <http://www.ed.gov/programs/equitycenters>.

- ²⁰ The Federal civil rights laws enforced by the Department include Title VI of the Civil Rights Act of 1964, which prohibits discrimination on the basis of race, color, or national origin; Title IX of the Education Amendments of 1972, which prohibits discrimination on the basis of sex; and Section 504 of the Rehabilitation Act of 1973 and Title II of the Americans with Disabilities Act of 1990, which prohibit discrimination on the basis of disability. OCR's Dear Colleague letter on discriminatory harassment under these statutes is available at <http://www2.ed.gov/about/offices/list/ocr/letters/colleague-201010.html>. The Department of Justice has jurisdiction to enforce Title IV of the Civil Rights Act of 1964, which prohibits discrimination on the basis of race, color, sex, religion, or national origin.

Chapter 104

CORRELATES OF BULLYING VICTIMIZATION AMONG IN-SCHOOL ADOLESCENTS IN THE 2005 BOTSWANA GLOBAL SCHOOL-BASED HEALTH SURVEY

ABSTRACT

Bullying victimization is a major public health problem among adolescents. It is associated with poor academic performance, anxiety, depression and suicidal behaviors. There are limited reports on victimization from bullying among Botswana adolescents. The purpose of this study was to determine the correlates for bullying victimization among school-going adolescents in Botswana. The 2005 Botswana Global School-based Health Survey (GSHS) data were obtained from the World Health Organization. A weighted analysis was conducted using statistical software (SPSS version 15.0). We estimated the prevalence of bullying victimization and conducted logistic regression analysis to estimate associations between the outcome (bullying victimization) and selected explanatory variables. Out of 2,165 in-school adolescents who participated in the study, 53.1% (54.2% males and 52.2% females; $p=0.086$) reported having been bullied in the last 30 days. In multivariate analysis, bullying victimization was positively associated with physical fighting (OR=2.17; 95% CI [1.73, 2.73]), truancy (OR=1.84; 95% CI [1.35, 2.50]), and

* Corresponding Author's Email: ssiziya@gmail.com.

alcohol drinking (OR=1.41; 95% CI [1.04, 1.91]). Victimization is prevalent among in-school adolescents in Botswana. Efforts to prevent and control bullying should take into consideration the factors identified in this study.

Keywords: Bullying victimization, physical fighting, truancy, alcohol, Botswana

INTRODUCTION

Where data are available, bullying victimization is prevalent globally with significant regional variations in the rates of victimization (1-2). In a study on bully victimization among in-school adolescents from five continents, Due et al (2) reported the highest 30 day prevalence for bullying victimization among boys was in Zimbabwe (70.2%), while Zambia had the highest prevalence for girls (67%). Adverse conditions positively associated with victimization from bullying include serious injuries (3), alcohol and drug use (4), truancy (5), depression (6) and suicidal behaviors (7).

Bullying victimization is common in Botswana among school going adolescents. Fleming and Jacobsen (4) report 30 day rates of being bullied as high as 53.0% with no sex difference (52.2% of females and 54.2% of males). They also considered factors (age, sex, symptoms of depression) associated with being bullied in their study but in their analysis they used the relative risk as a measure of the magnitude of association. Unfortunately the relative risk is not an appropriate measure of association in cross sectional studies. The purpose of this study was to re-analyze the data on correlates for bullying victimization among school-going adolescents in Botswana so that we may provide public health officers, school health and administration officials and other stakeholders with correct results for use in interventions.

METHODS

This study was based on a secondary analysis of data from the Botswana Global School-based Student Health Survey (GSHS) that was conducted in 2005. The 2005 Botswana GSHS was a school-based survey which included students in classes with the majority ages of 13-15 years. A two-stage cluster sampling design was used to produce data that were representative of students in the country. At the first stage, schools were selected with probability proportional to enrolment size. At the second stage, classes were randomly selected and all students in selected classes were eligible to participate. There was no replacement of students who were not available despite being in the selected schools. Students self-completed the questionnaires and the responses to questions were indicated on a computer scannable answer sheet.

In order to assess history of victimization from bullying, the question that was asked was: During the past 30 days, on how many days were you bullied? Possible responses included 0 days or any number of days. In terms of involvement in a physical fight, students were asked the question: During the past 12 months, how many times were you in a physical fight? Options included 0 times, one up to 12 or more times.

Ethical considerations

These data were obtained from the World Health Organization. The study was approved by the Botswana Ministry of Health. Parents were informed of the study through a letter, and students gave verbal consent to participate in the survey. To preserve individual confidentiality, the questionnaire was anonymously self-reported by the students.

Data analysis

Cases with missing values were not considered in the analysis. A weighting factor was used in the analysis to account for differences in the probability of selecting a school and classroom, and to account for differences in non response rates for various strata.

Data were first analyzed using SPSS version 11.5. Unweighted frequencies and their weighted percentages are reported. For the main outcome (bullying victimization), we recoded the responses in two categories: 0 for not having been victimized in the past 30 days, and 1 for having been victimized in the past 30 days. We conducted bivariate and multivariate logistic regression analyses in order to estimate associations between independent factors and the outcome variable. The hypotheses were "There were no significant associations between socio-demographic factors and bullying victimization". We report prevalence of bullying victimization within the past 30 days of the survey as well as the unadjusted odds ratios (OR) and adjusted odds ratios (AOR) together with their 95% confidence intervals (CI).

RESULTS

A total of 2,165 students participated in the 2005 Botswana GSHS; and 1829 had information on whether they were bullied or not. Overall, 42.4% were depressed; 22.5% consumed alcohol; and 8.7% had used illicit drugs. More than 1 in five (22.5%) participants reported having missed classes without permission. Altogether, 53.1% (54.2% of male and 52.2% of female) participants reported having been bullied in the previous 30 days to the survey. Further description of the sample by gender is shown in Table 1.

Table 2 reports associations between being bullied and selected factors. Being bullied was positively associated with having engaged in physical fighting (OR=2.17; 95% CI [1.73, 2.73]), self reported feelings of depression (OR=1.40; 95% CI [1.16, 1.77]); truancy (OR=1.84; 95% CI [1.35, 2.50]); and alcohol drinking (OR=1.41; 95% CI [1.04, 1.91]).

DISCUSSION

In a study of bullying victimization among in-school adolescents in Botswana, we found that 53.1% of the respondents were bullied in the last month. This prevalence is higher than the average (32%) for 66 countries and territories from five continents (2). In Africa, that prevalence is lower than 62.8% reported in Zambia (9), but higher than 40.1% in Ghana (8) and 39.6% in neighboring Swaziland (5).

Table 1. Socio-demographic characteristics and bullying victimization of the Botswana study sample, 2005

Factor	Male n (%)	Female n (%)	Total (%)
Age (years)			
< 14	78 (8.0)	131 (11.0)	209 (9.7)
14	190 (19.5)	302 (25.3)	492 (22.7)
15	319 (32.8)	372 (31.2)	6 (1.9)
16 +	385 (39.6)	388 (32.5)	773 (35.7)
Physical fight			
No	458 (47.1)	691 (58.3)	1149 (53.3)
Yes	514 (52.9)	494 (41.7)	1008 (46.7)
Parental supervision			
No	326 (34.5)	348 (30)	674 (32)
Yes	618 (65.5)	811 (70)	1429 (68)
Depression			
No	569 (59.6)	651 (55.7)	1220 (57.5)
Yes	385 (40.4)	518 (44.3)	903 (42.5)
Cigarette smoking			
No	817 (89)	1083 (95.2)	1900 (92.4)
Yes	101 (11)	55 (4.8)	156 (7.6)
Alcohol drinking			
No	596 (75.9)	795 (78.8)	1391 (77.5)
Yes	189 (24.1)	214 (21.2)	403 (22.5)
Drug use			
No	840 (86.3)	1138 (95.4)	1978 (91.3)
Yes	133 (13.7)	55 (4.6)	188 (8.7)
Truancy			
No	665 (70.2)	950 (80.3)	1615 (75.8)

Yes	446 (54.2)	525 (52.2)	971 (53.1)

We found that bullying victimization was positively associated with reported depression, having engaged in physical fighting, truancy, and alcohol drinking. In a study of the association between bullying and psychological health among senior high school students in Ghana, Owuso et al found that bullying victimization was positively associated with depression, suicide ideation, and loneliness (8). The association between bullying victimization and physical fighting was reported previously in other settings such as Zambia (9), Philippines (10) and China (11). In a study of the association between physical bullying victimization and physical fighting among Filipino school going adolescents, Rudatsikira et al reported a dose-response relationship between the two (10). Previous studies have reported the relationship between bullying victimization and alcohol use and other substances (12,13).

In this study, there was no significant gender difference in bullying victimization. Some studies have reported similar findings (8,10) while others have reported that males were more

likely to be bullied than females (9,11). What is consistent in the literature is the gender difference in the types of bullying victimization; males are more at risk for physical victimization while females are more at risk of relational or emotional victimization (14-15).

Table 2. Factors associated with being bullied among in-school adolescents in Botswana, 2005

Factor	Bullied n (%)	OR ¹ (95% CI ³)	AOR ² (95% CI)

Limitations and strengths of the study

The present study has several limitations and strengths. Data were collected through self-reports. To the extent that study participants mis-reported, intentionally or not, our findings

may be biased. The study design was cross sectional which limits us from ascribing causation between the outcome and explanatory variables. It is also important to note that different studies have defined bullying differently. For instance, Sourander et al (16) defined bullying as "an aggressive act embodying an imbalance of power in which the victims cannot defend themselves accompanied by an element of repetition." Our study only asked whether students had been bullied. However, the sample size was large thus improving precision of the effect measure estimates. That this study is a secondary analysis of existing data can be both a strength and a weakness. A strength in that the subjects' responses could be accurate as study participants may not have anticipated any links between outcome variable and explanatory variables, hence truthful reporting; and a weakness in that there are likely to be several unmeasured confounders that a primary study could have planned to measure.

CONCLUSION

In this study, we found that bullying victimization was prevalent among school-going adolescents in Botswana. Efforts to prevent and control bullying should take into consideration the factors identified in this study.

ACKNOWLEDGMENTS

We thank the World Health Organization for availing the data for further analysis and the students for their participation in the survey.

Chapter 105

BULLYING BEHAVIOUR FOLLOWING STUDENTS’ TRANSITION TO A SECONDARY BOARDING SCHOOL CONTEXT

Leanne Lester*, PhD, David J Mander, PhD and Donna Cross, ED

ABSTRACT

This chapter investigated the prevalence and types of bullying behaviour that boarding students experienced during the transition to a secondary boarding school. Data on 76 male and 74 female boarding students in Grades 7, 8 and 9 was used from a larger longitudinal study of 3,462 students. An examination of the combined dataset prevalence figures found that boarding students reported experiencing significantly higher victimization and perpetration of bullying behaviours than non-boarders after their transition into secondary school. The victimization was found to predominantly take the form of verbal bullying. The increase in the prevalence of bullying behaviours over the course of the first year of secondary school suggests that prior to and during this transition period is the most critical time to implement bullying prevention programs. Due to the sustained nature of bullying behaviour over the first two years of secondary school it is recommended that boarding schools develop clear policies and consistent procedures and practices to address bullying and encourage help seeking behaviours. Similarly these students will need support to build positive relationships with their peers to seek assistance from others early and often if they are experiencing difficulties.

INTRODUCTION

Adolescence is a developmental stage in life that is associated with major cognitive, emotional, physiological and social change. Adolescence coincides with the onset of puberty and is typically described by parents as a period in which they attune to their child's growing need for autonomy and greater desire to source social support from same aged peers. Many adolescents look forward to the transition to secondary school as it represents a period of possibilities; a time to master new academic, social, emotional and extracurricular activities (1). However, adapting to multiple formal and informal organizational and social relational structures that are inextricably linked with the high school environment can prove particularly daunting to transitioning students (2).

Transitioning from primary school to a secondary boarding school adds another layer of complexity to secondary school life, as students have to simultaneously adjust from a situation where home and school are separate, into a setting where a temporary new home and schooling are merged together. Although some boarding students have reported the transition to boarding school has given them a greater appreciation for family and home, other students have equally reported that the process of adapting to new boarding school duty of care rules and regulations can be difficult as they tend to reduce privacy and personal freedom. Moreover, it commands boarding students to almost instantly display high levels of self-reliance, life skills and independence (3)". Similarly, boarding school requires adjusting from a situation where contact with family members occurs on a daily face-to-face basis to a situation where for extended periods of time contact is limited to contact via telephone, Skype and other means of communication such as email and text messages. Others have also described this change as shifting from vertical relationships with parents to horizontal relationships with peers at school and within the boarding house (3).

Friendship and peer support are needed for the development of social, emotional and mental health and have been identified as important contributors to a successful school transition (4). Peers not only provide support, but information and guidance (5). However, a peak in bullying victimization occurs following the transition to secondary school (6) largely resulting from the pressure to attain high social status and the formalization of relationships and social roles in new social groups (7). The seriousness and negative impact of school bullying is well known contributing to significant physical, psychological and social wellbeing problems (8) which in turn effects academic performance (9).

In boarding schools, a significantly larger amount of time is spent with peers (24 hours a day, 7 days a week) compared to day students (6 hours a day, 5 days a week). Arguably, the residential boarding context provides greater opportunity for bullying to occur (10,11). Some have described bullying at boarding school as 'relentless' given that targets have fewer choices to minimize their exposure to bullying, with bullying often following the target from the day school setting into the residential setting (3). Evidence suggests bullying can become institutionalized into the culture of boarding schools that are not vigilant to its presence (11). Poynting and Donaldson (10) described peer-to-peer bullying in one Australian elite boys' only boarding school as endemic and entrenched, taking the form of ridicule and racial slurs, physical and sexualized assault, all contained within a culture of intimidation and non-disclosure. In these instances bullying has been justified through language that constructs it as a 'tradition' or 'initiation' and analogous with a normal a rite of passage (12).

The long term negative mental health and life trajectory implications for individuals that experience bullying and also perpetrate bullying while at school are increasing being acknowledged (13). Bullying at boarding school has been linked to high levels of shame, anxiety, thoughts of revenge, and experiencing relationship difficulties as adults (3). Despite these apparent harms, a dearth of current information on bullying behaviour in boarding schools exists. This paper uses quantitative data to examine the patterns of bullying behaviours in Australian boarding schools during the initial experience of transition and the year immediately following transition. The primary aim of this study is to determine whether a difference exists in the prevalence and type of bullying behaviours between boarding and non-boarding students and examines help seeking behaviours of those who have been bullied.

OUR STUDY

The data in this study were taken from a larger longitudinal study, the Supportive Schools Project (SSP) conducted in Perth, Western Australia (WA). SSP aimed to develop and implement whole-of-school strategies to reduce the prevalence of frequent bullying behaviours as well as positively influence common mediators of bullying. The study was approved by the ethics committee of the administering institution and the relevant Catholic Education school authorities.

Cohort data were collected during the Supportive Schools Project (SSP) from 3,462 students from 21 of the 28 Catholic secondary schools in WA. The seven schools that declined to participate in the study cited other priorities within their school and demanding staff workloads. All invited CEO schools were stratified according to the total number of students enrolled at the school and each school's Socio-Economic Status (SES) to help to control for the influence of these two factors on student bullying behaviour. These schools were randomly selected and randomly assigned to an intervention or comparison group. To collect data relating to their pre-transition experience, all Grade 7 students enrolled to commence in Grade 8 at each of the 21 participating secondary schools received a baseline survey while in Grade 7 at their respective primary schools. A combination of active and passive consent resulted in 93% of parents whose children were enrolled in the 21 recruited secondary schools consenting to their child participating in the study.

The student cohort was surveyed at the end of Grade 7 (mean age 12 years), the beginning and end of Grade 8 (mean age 13 years old) and the end of Grade 9 (mean age 14 years old). In total, 3,462 (92% of the total recruited) students completed questionnaires at least at one time point with 3,123 (90%) responding to at least three of the four data collection points. One half of the students surveyed were male and 70% attended a co-educational secondary school versus a single sex secondary school. A total of 5% of students (76 males, 74 females) identified themselves as living away from home to complete their secondary education at the secondary schools involved in the SSP.

Measures

Boarder Status. Students in Grades 8 and 9 were asked whether they were living away from home while going to school this year. Those who indicated they were living away from home in Grade 8 have been classified as 'boarders'.

Bullying victimization and perpetration. A global measure of victimization was obtained by asking students 'In the previous term, how often did another student or group of students bully you?' with the response options recorded on a 5 point scale (1=never, 2=only once or twice, 3=every few weeks, 4=about once a week, 5=most days). Similarly a global measure of perpetration was obtained. The type of bullying victimization was assessed using a nine-item categorical index adapted from Rigby and Slee (14), Olweus (15) and from the 2004 Youth Internet Survey (16). Students were asked how often they were bullied through physical (hit, kicked and pushed around; had money or other things broken or taken away from them; made to feel afraid they would get hurt), verbal (made fun of and teased in a hurtful way; called mean and hurtful names), relational (students ignored them, did not let them join in, or left them out on purpose; and students told lies about them and tried to make other students not like them) or cyber (were sent mean and hurtful text (SMS) messages; were sent mean and hurtful messages on the internet) means during the prior term at school. For each item students were asked how often they were bullied, rating each item on a 5 point scale (1=never, 2=only once or twice, 3=every few weeks, 4=about once a week, 5=most days). Frequent victimization was defined as every few weeks or more often. The type of perpetration was assessed using a similar nine-item perpetration index which asked students how often they were bullied by others in the different ways listed.

Students were also asked how often they were bullied by other students in various year levels. Those students who reported being bullied were also asked if they asked for help, from whom they asked for help (parents, friends, teachers, school staff) and if things got better after they asked for help.

Bystander behavior was assessed through the question 'If you saw a student being bullied, what did you do?' with the response choices being: I joined in the bullying; I watched the bullying; I walked away; and I tried to get help. Students were also asked whether they: thought the bullying was OK; thought it was none of their business; didn't know what to do; or thought they should help the student being bullied

Lastly, students were asked how serious they thought staff took bullying: they didn't know; not at all seriously; somewhat seriously; very seriously; or extremely seriously.

Statistical analysis

Analyses were conducted using SPSS v21. Chi-square analyses were used to determine differences in categorical variables with respect to boarders and non-boarders and gender.

FINDINGS

At the end of Grade 7, 65% of students reported they were not victimized, 25% reported they were victimized once or twice and 11% reported frequent victimization (every few weeks

or more often in the past 10 weeks) (Table 1). The majority of students (71%) reported they did not bully others, 26% reported they bullying others once or twice and 3% reported frequent perpetration (every few weeks or more often in the past 10 weeks).

Boarders vs non-boarders: Target of bullying

No significant differences were found for the frequency of bullying victimization between boarders and non-boarders at the end of Grade 7. However, after the transition to secondary school, significant differences were found for the frequency of victimization among students who were boarders and those who were day students only. Boarders reported more frequent victimization at the beginning of Grade 8 ($X^2=21.965$, $p<0.001$), the end of Grade 8 ($X^2=17.881$, $p<0.001$), and the end of Grade 9 ($X^2=14.316$, $p=0.001$) than non-boarders. While the increase in reported frequent victimization over the first two years of secondary school was similar for boarders and non-boarders, by the end of Grade 9 twice as many boarders were frequently victimised than non-boarders, with one in five boarders reporting frequent victimization compared to one in 10 non-boarders by the end of Grade 9.

Perpetrator of bullying

Similarly, significant differences were found between boarding and non-boarding students and the frequency of perpetration in which they engaged after their transition to secondary school. Boarders reported engaging in more frequent perpetration of bullying at the beginning of Grade 8 ($X^2=6.068$, $p=0.048$), the end of Grade 8 ($X^2=35.243$, $p<0.001$), and the end of Grade 9 ($X^2=10.567$, $p=0.005$) than non-boarders. By the end of Grade 9, 14% of boarders reported frequent perpetration compared to 8% of non-boarders.

Target/perpetrator of bullying

Similarly, boarders who were victimized and who also perpetrate (bully-victims) also reported they had more frequent involvement in bullying behavior at the beginning of Grade 8 ($X^2=15.004$, $p=0.001$), the end of Grade 8 ($X^2=26.427$, $p<0.001$), and the end of Grade 9 ($X^2=13.859$, $p=0.001$) than non-boarders.

Boarders, gender and bullying behavior

A significantly higher proportion of male boarders reported frequent victimization ($X^2=6.908$, $p=0.032$) at the end of Grade 9 compared to female boarders (27% compared to 14% respectively). A significantly higher proportion of male boarders also reported engaging in frequent perpetration at the beginning of Grade 8 ($X^2=13.847$, $p=0.001$) and end of Grade 9 ($X^2=7.576$, $p=0.023$) compared to female boarders (beginning of Grade 8: 11% compared to 0% respectively; end of Grade 8: 22% compared to 6% respectively). Similarly, a significantly

higher proportion of male boarders reported bully-victim behaviours at the beginning of Grade 8 ($X^2=6.073$, $p=0.048$) compared to female boarders (15% compared to 3% respectively).

Type of bullying experienced by boarders

The most frequently reported forms of bullying reported to be experienced by boarders at the beginning of Grade 8 was verbal (being made fun of and teased and called mean names) and relational means (being ignored and excluded and having lies told about them to make students not like them) (Table 2). Physical and cyber bullying became more prevalent at the end of Grades 8 and 9. All forms of bullying increased in prevalence over the first two Grades of secondary school.

With respect to boarders only, no significant differences were found between males and females and the types of victimization they experienced at the end of Grade 7 and the beginning of Grade 8. However, at the end of Grade 8, a significantly higher proportion of males reported verbal bullying than females. Similarly, by the end of Grade 9 a significantly higher proportion of males reported verbal, and physical bullying than females.

A significantly greater proportion of boarding students than non-boarding students reported verbal and relational bullying in both Grades 8 and 9. By the end of Grade 9 a significantly greater proportion of boarding students reported being physically bullied than non-boarding students.

Types of bullying perpetrated by boarders

The most frequent forms of bullying perpetration reported by boarders was verbal and relational bullying (Table 3). Perpetration of physical and cyber bullying became more prevalent at the end of Grades 8 and 9. All forms of bullying perpetration increased in frequency over the first two Grades of secondary school.

At the beginning of Grade 8, a significantly greater proportion of boarding students reported verbally and physically bullying others compared to non-boarding students. This pattern continued to the end of Grades 8 and 9 with a significantly greater proportion of boarding students than non-boarding students reporting verbal, physical, relational, and cyber bullying.

At the beginning of Grade 8, boarders reported being victimized by students in Grades 8, 9 and 10 (Table 4). However, by the end of Grades 8 and 9, boarders predominantly reported being victimized by students in their own grade levels.

Table 3. Frequency and type of perpetration by boarders from the beginning of Grade 8 to the end of Grade 9.

%		Beginning of Grade 8			End of Grade 8			End of Grade 9

Table 4. The context of bullying, help seeking and bystander behaviours of boarders.

%(n)	Beg of Grade 8	End of Grade 8	End of Grade 9
Who are they being bullied by?			
Grade 8	29.6(40)	47.6(68)	14.4(18)
Grade 9	20.6(26)	26.8(37)	42.4(53)
Grade 10	18.9(24)	25.9(36)	21.7(26)
Grade 11 or 12	15.4(20)	18.6(26)	17.4(21)
Don't know	9.4(10)	12.7(15)	13.2(14)
When bullied, asked for help	26.7(16)	29.4(20)	25.0(15)
Bystander behaviour			
Thought bullying was OK	0.7(1)	2.7(4)	4.0(6)
Thought bullying was none of my business	21.3(32)	21.3(32)	10.7(16)
Thought I should help student being bullied	54.7(82)	30.7(46)	18.0(27)

Help seeking and bystander behaviour and perceptions of staff

Over one-quarter of boarders who reported being bullied did not ask for help. The majority of boarders in Grades 7 and 8 who witnessed another student being bullied, thought they should help the student being bullied and tried to help. However, by the end of Grade 9, a greater proportion of boarders who witnessed others being bullied watched the bullying rather than tried to help and thought it was none of their business.

At the beginning of Grade 8, 49% of boarders thought staff took bullying very or extremely seriously, 9% somewhat seriously, 4% not at all seriously, and 39% did not know how serious staff took bullying.

DISCUSSION

This study found significantly higher bullying prevalence rates in boarders after their transition to secondary school. Given, longitudinal research shows that adolescents who are victimised are more likely to experience depression, anxiety, psychosomatic complaints and suicidal ideation (8), and that boarding students are found to have lower levels of mental and emotional wellbeing than non-boarders after the transition to secondary school (17), it seems critically important to prevent and manage these behaviours within the boarding school context.

Unlike non-boarding students whose reported prevalence data was similar to national prevalence data (6), boarders reported significantly higher victimization than the national data and this prevalence increased over time. The increase in prevalence of bullying behaviours following transition and then over time for boarders suggests that their transition to secondary school combined with their transition to boarding school is opportune to skill school staff and students to address bullying behaviours. A case study of an Australian boy's board school (10) found the school minimised and controlled the disclosure of bullying incidents, creating a culture that both tolerated and seemingly admired students who bullied. Students from this boarding school claimed the older students victimised those younger, creating a tradition of bullying within the school. The identification of indecent assaults, sexualised bullying and violence at this boarding school resulted in many Australian private boarding schools reviewing their duty of care and residential supervision practices and procedures (18). Likewise, in response, the Australian Boarding Schools Association (ABSA), which has over 95% of Australian boarding schools as members, developed a Duty of Care: A Certificate Course in Residential Education (19) which set minimal industry based standards (National Boarding Standards (NBS)) in professional training for staff at boarding schools. These standards enable students to be more socially responsible by encouraging pro-social behaviour, discouraging poor behaviour, providing effective anti-bullying policies, and encouraging responsible use of technology (20). While these standards and others developed since are important, a sustainable ongoing strategy of review by schools and governing bodies to prevent and manage bullying is required.

Boarding students in this study perpetrated more bullying than day students. Boarding school practices and policies need to clearly define what social behaviours it expects students to engage in and what constitutes bullying behaviour and relay this information to all staff and students. Boarding school policies developed in conjunction with boarding students which

discourage bullying behaviours, and identify consequences for bullying, need to be administered consistently. Negative outcome expectancies, including adults finding out and adult and peer disapproval, are strong motivational forces to prevent involvement in bullying behaviours (21). Students are less likely to engage in aggressive behaviours if they perceive there will be negative consequences (22). Less than a half of the boarding students in this study believed staff took bullying seriously, with a large proportion of boarders who were victimised not seeking help. Encouraging and enhancing the ability of adults to prevent, detect and intervene in bullying incidents, enabling students to support victimised students, and easy reporting of bullying, will help to reduce victimization (23).

This study showed that boarders who witnessed bullying in Grade 8 thought they should try to help, with this attitude decreasing over time. Participation in perpetration can also be discouraged through encouraging a pro-victim attitude (including support for the victim, empathy towards the victim and disapproval of bullying behaviours) (24). To increase pro-victim behaviour, supporters (those who comfort, support or stand up for those being victimized) need to be acknowledged as positive models for the peer group (25) with students encouraged to perceive all cases of bullying as severe and unjust.

Given, that students in this study were surveyed at the end of Term 1 (10 weeks into the school year) in Grade 8 and again in Term 4 of Grade 8, this six month period resulted in large increases in the prevalence of bullying behaviors for boarders. These changes may be related to changes in boarder attitudes towards bullying due to inconsistent enforcement or lack of bullying policies and procedures. Transition activities and organizational support by boarding schools tend to taper off after the first 10 weeks of the school year as students' are encouraged to take greater responsibility and to self-manage. The findings from this study suggest it may be necessary to provide mores sustained social support to boarders for the duration of Grade 8. This appears to be a critical time in particular to implement social development programs, clarify boarding house policies and procedures, consistently administer rules, and encourage help seeking behaviours. Preventative steps such as pre-transition seminars and forums for prospective families for new boarding students which outline bullying policies and procedures are also encouraged. The large difference in bullying prevalence between boarders and non-boarders, suggests further research is necessary to explore student socialization processes and staff practices in the residential context and the impact these have on boarding students social and emotional wellbeing and mental health during transition.

Strengths and limitations

There are several strengths of this study. The longitudinal nature of the quantitative research design over the transition from primary into secondary school enabled the investigation of bullying at a time that can be challenging for boarders and non-boarders alike. Moreover, these findings are robust due to the large proportion of boarders (89%) and non-boarders (90%) who completed questionnaires in at least three of the four data collection points. The limitations of this study include relying on student self-report of bullying victimization and perpetration. The quantitative research was conducted with a sample of Catholic secondary schools within the Perth metropolitan area which affects the generalizability of results, given they represent only 11% of all secondary schools (n=186) in Perth, Western Australia. School activities over the transition period will likely influence students' experiences. Students were

classified as 'boarders' in this study if they indicated they were living away from home while going to school.

These results, however, draw attention to the prevalence of bullying behaviour in boarder populations and suggest opportunities to intercede in the post transition period.

ACKNOWLEDGMENTS

We thank Melanie Epstein, Erin Erceg, and Stacey Waters for their contributions to the Supportive Schools Project (SSP) project, and the SSP study schools and their staff, parents, and students. The SSP Project and this study were funded by the Western Australian Health Promotion Foundation (Healthway) and the research supported by the Child Health Promotion Research Centre (CHPRC) at Edith Cowan University, Western Australia.

ABSTRACT

Data on bullying/cyberbullying and depression/suicide ideation among youth is usually collected via paper-and-pencil questionnaires delivered in classrooms. In recent years data collection methods for psychological questionnaires have seemingly shifted from the classical paper-and-pencil method to web-based questionnaires. There are numerous advantages to web-based methods; however, the exact circumstances in which this method affects data quality are not yet fully understood. In this chapter we address the question of whether the medium by which data is collected affects results, specifically concerning bullying, cyberbullying, depression and suicide ideation among adolescents. Study group: A total of 230 students participated in the study. Half (n=115) were recruited online and completed a web-based survey. The other half (n=115) were recruited from five different middle schools and high schools across Israel and completed a paper-and-pencil survey. The participants who completed the paper-and-pencil survey were matched to the online participants in terms of their age, gender and parental occupation status. Methods: Data from both samples were compared and significant differences were further investigated. Results: General cyber-victimization was more prevalent among participants who answered paper-and-pencil questionnaires. Being harassed in virtual chat rooms and suffering from rumors being spread online were the specific types of cyber-victimization that were more prevalent on paper-and-pencil questionnaires. Depression and harassment via e-mail were more prevalent among online participants. Conclusions: Recruiting participants online has many advantages but it is important to understand the limitations of this sampling method, especially the extent to which it is possible to generalize findings.

INTRODUCTION

Bullying, cyberbullying, depression and suicide ideation are major concerns regarding adolescents, particularly given that suicide is the third leading cause of death among American adolescents (1). Moreover, depression and suicide ideation are risk factors for suicide completion (1) as studies show that roughly 1 out of 8 adolescents suffered from depression (2) and 15.8% of high school students seriously considered attempting suicide (3).

In a nationwide survey conducted in 2011, 20% of high school students reported being bullied and 16% reported being cyberbullied during the past 12 months (4). Most of the data for the research on bullying/cyberbullying and depression/suicide ideation among youth has been collected using classical paper-and-pencil self-report questionnaires. This method is expensive, complicated and time consuming; and therefore researchers are turning to more cost-effective alternatives (5). With the growing ubiquity of Internet access (6), an increasing number of researchers are finding ways to utilize the Internet in order to conduct research in their fields. Research on bullying/cyberbullying and depression/suicide ideation is no exception. Recent studies in this field have started collecting data using web-based questionnaires (7,8). In order to safely advance from paper-and-pencil to web-based research in this field, it is important to systematically compare the two.

The advantages of conducting web-based research are plentiful. Firstly, it provides access to larger and more diverse samples. In addition, data entry in web-based research is done indirectly by participants themselves (9). Lastly, it has been said to provide a heightened sense of anonymity (10) which is considered advantageous, as it encourages honesty when touching sensitive topics (11). However, this heightened sense of anonymity is becoming increasingly harder to assume. People are becoming more knowledgeable about the potential for infringing on anonymity in cyberspace. Therefore, this may theoretically interfere in truthful self-reporting.

The great advantages and promise that web-based research brings does not come without a price. Samples are still confined to participants who own a computer and have Internet access (12). In addition, recruitment techniques, such as advertising in blogs, forums, or web-sites, make it very difficult to achieve a random sample (13). Furthermore, participants are not in a controlled environment during the experiment, it is impossible to verify demographic information, it is difficult to estimate response rates, and finally, with no experimenter watching over participants, ethical problems may arise (13).

Many studies have compared data that were obtained online against data obtained in the lab and have mostly supported the notion that the quality of data (e.g., sample diverseness, responders seriousness, etc.), obtained online is as good as, if not better, than data obtained in the lab (14). Studies comparing data collected using web-based questionnaires and paper-and-pencil questionnaires on potentially sensitive personal matters drew the same conclusion (15). Computer based surveys may be preferable when targeting sensitive issues as the sense of anonymity increases and social desirability (i.e., a tendency to answer questionnaires in a socially acceptable or favorably viewed way) decreases (15,16). Furthermore, web-based questionnaires have been shown to reliably detect depressive disorders (17) and other mental disorders (18).

Comparing data collection methods among adolescents is necessary for several reasons. First, the popularity of web-based research among adolescents is rising as conducting paper-

based research consumes important school time which is also very hard to obtain. Second, adolescents are growing up surrounded by web-based interfaces and spend more time in front of screens, now more than ever (19). For adolescents, answering web-based questionnaires might be becoming more natural than the paper-based alternative.

To the best of our knowledge, most studies have not been conducted among adolescents and while some compared data on the topic of bullying, none have used an online self-selected sample nor have compared differences for cyberbullying.

OUR STUDY

A total of 230 Israeli middle school and high school students participated in the study. Half of the students ($n=115$) completed a web-based survey online and the other half completed a paper-based survey. The paper-based survey completers were matched to the online participants in the terms of their age, gender and parental occupation status. In this regard, the participants in both groups ranged in age from 14-17 years of age ($M=16.06$, $SD=1$); 122 were male (53%) and 108 were female (47%); 22 were in 9th grade, 42 were in 10th grade, 66 were on 11th grade and 100 were in 12th grade. Out of 230 participants, 198 (86.1%) reported that both of their parents were working.

Procedure

This study was approved by the institutional review board of the Interdisciplinary Center Herzliya. Online participants were recruited via midgam.com, an Israeli web-based survey platform. When signing up to midgam.com, under-aged participants must obtain their parents signature in order to complete their registration. Before answering the questionnaires, all participants signed an online informed consent form. Subsequently, participants were requested to complete the questionnaire in one session and were also informed that the website allows only one entry per participant. All participants were reimbursed 20 NIS (around 6 USD) for their participation in the study.

A paper-and-pencil survey was conducted in 5 middle schools and high schools across Israel as part of a research on the same topic (20). After obtaining approval from a) the Chief Scientist of Israel's Ministry of Education and b) the school principals, all of the participants' parents were contacted via mail and e-mail. Parents were notified about the study and were asked to sign a form if they did not want their child to participate in the study. Students were asked for their consent in class. Of the 757 participants who completed the questionnaire, 115 were selected to statistically match the online participants in age, sex and parental occupation status.

Measures

Anonymous self-report questionnaires were used to assess participants' experience of bullying, cyberbullying, depression and suicide ideation.

The demographic questionnaire obtained information regarding age, gender and parental occupation status.

Bullying and cyberbullying behavior was assessed using a questionnaire which was previously used by Sourander and colleagues (21). Participants were asked about their involvement in bullying behavior during the past six months, both as a bully and as a victim. The four answer options were 1- never; 2- less than once a week; 3- more than once a week; and 4- almost every day. Participants were regarded as bullies if they reported bullying others during the past six months, either in or out of school, to any extent (i.e., any answer other than "never"). If participants reported being bullied by others during the past six months, in or out of school, they were regarded as victims. Similarly, participants were regarded as cyberbullies or cyber-victims if during the past six months they cyberbullied others or were cyberbullied by others, respectively. In addition to bullying and cyberbullying in general, more specific questions were asked concerning explicit acts of traditional bullying (e.g., hitting, name calling, stealing money, etc.) and cyberbullying (e.g., threatening, rumor spreading, ridiculing, etc.).

Depression was assessed using the Mood and Feelings Questionnaire (MFQ). This self-report questionnaire examines recent depressive symptoms. Participants are asked to mark how true 33 different statements are in accordance with how they have been feeling over the past two weeks (22). Participants can regard each statement either as 0- not true; 1- sometimes; or 2- true. MFQ scores may range between 0-66; this score positively correlates with the prevalence of depressive symptoms. The optimal cut-off point for depressive disorders has been established as 26 or more (23). This point was used to dichotomously differentiate participants as either depressive or non-depressive.

Suicide ideation. In assessing whether a participant had suicidal ideation, any answer other than "Not True" on items 16-18 of the MFQ was taken as indicating passive suicidal ideation. These items included the statements "I thought that life wasn't worth living", "I thought about death or dying" and "I thought my family would be better off without me". Any answer other than "Not True" on item 19 of the MFQ, which held the statement "I thought about killing myself" was regarded as having active suicidal thoughts.

Analysis

To evaluate whether data collected online was significantly different from data collected via paper-and-pencil questionnaires, a series of χ^2 tests for independence was conducted. The tests compared the prevalence of bullying behavior, victimization, cyberbullying, cyber-victimization, depression, passive suicide ideation and active suicide ideation, between the online and pen-and-paper participants. To better understand the difference between the samples in cyber victimization, an additional series of χ^2 tests for independence was conducted.

FINDINGS

Table 1 presents the differences between the online sample and the paper-and-pencil sample regarding prevalence of different behaviors. Bullying, victimization, cyberbullying,

passive suicide ideation and active suicide ideation were not significantly different. However, cyber-victimization and depression did significantly differ.

Table 1. Prevalence of behavior among participants in both surveys.

Type of behavior	Online Participants	Paper-and-pencil Participants	Sig of χ^2
Bullying	N=110; 18 (16%)	N=114; 23 (20%)	.286
Victimization	N=110; 24 (21%)	N=114; 36 (31%)	.067
Cyberbullying	N=107; 3 (3%)	N=115; 9 (8%)	.086
Cyber-victimization	N=107; 9 (8%)	N=114; 23 (21%)	.01
Depression	N=115; 21(18%)	N=115; 11(10%)	.043
Passive suicide ideation	N=106; 29 (27%)	N=114; 28 (25%)	.375
Active suicide ideation	N=106; 10 (9%)	N=114; 8(7%)	.342

Table 2 presents the comparison between specific cyber-victimization experiences. Participants who answered paper-and-pencil questionnaires reported suffering from rumors being spread about them online and being cyberbullied in virtual chat rooms more than did online participants. More online participants, however, reported being cyberbullied via e-mail. All other comparisons were not significantly different.

Table 2. Prevalence of different types of cyber-victimization among participants in both surveys.

Type of behavior	Online Participants	Paper-and-pencil Participants	Sig of χ^2
Ignored by others	N=107; 15 (14%)	N=115; 19 (17%)	.371
Disrespected by others	N=107; 14 (13%)	N=114; 18 (16%)	.353
Called names by others	N=102; 9 (9%)	N=103; 7 (7%)	.39
Had rumors spread by others	N=107; 10 (9%)	N=115; 21 (18%)	.042
Threatened by others	N=107; 4 (4%)	N=114; 5 (4%)	.54
E-mail bombed by others	N=107; 6 (6%)	N=115; 7 (6%)	.554
Picked on by others	N=107; 5 (5%)	N=115; 9 (8%)	.246
Ridiculed	N=107; 12 (11%)	N=115; 19 (17%)	.172
Scared for safety	N=115; 7 (6%)	N=115; 5 (4%)	.384
Virtual chat room	N=107; 12 (11%)	N=115; 24 (21%)	.038
Instant messaging service	N=107; 6 (6%)	N=115; 7 (6%)	.554
E-mail	N=107; 5 (5%)	N=115; 0 (0%)	.025
Phone text messaging	N=104; 2 (2%)	N=115; 0 (0%)	.224
Discussion group	N=107; 7 (7%)	N=115; 9 (8%)	.458
Chat room	N=107; 2 (2%)	N=115; 8 (7%)	.064

DISCUSSION

The current preliminary results indicate that the shift in the social sciences to web-based research must proceed with caution. Our results on bullying, victimization, cyberbullying and suicide ideation generally support previous studies (14) by indicating that web-based research is suitable for adolescents, but further analysis is required, specifically for depression and cyber victimization.

The finding that in the online sample more participants reported being depressed could be explained by the sample characteristics. One major disadvantage of web-based research is that currently there is no method to produce a random sample of Internet users (5). It is possible that adolescents who answer Internet questionnaires spend more time than average online. Intense Internet use has been found to correlate with major and minor depressive symptoms across age, gender and household income (24).

The finding that the online sample reported less cyber-victimization, however, is not consistent with studies indicating that intense Internet use is associated with an increased likelihood of suffering from cyber-victimization (25). According to the leverage-saliency theory of survey participation (26), participants tend to avoid surveys on negatively predisposed topics; hence, the finding that cyber-victimization prevailed less among online participants may be due to a biased sample in which cyber-victims were reluctant to participate in the current online survey. A study investigating cyber-victims' coping strategies found that after being cyberbullied, 20% reported staying offline for a period of time (8). This too, may affect the prevalence of cyber-victims in online studies. Other than sample characteristics, the medium by which data was collected may also play a part in explaining the differences. As suggested by a number of studies, web-based data collection methods may influence responses on computing related items (27,28). For example, Carini et al (29) found that students' responses to a questionnaire regarding the degree of engagement in their college experience were more favorable on web-based than on paper-and-pencil questionnaires. Notably, the largest effect they found was generated by the computing and information technology scale.

In our analysis of different types of cyber-victimization we found that more participants from the paper-and-pencil group reported that rumors were being spread about them. This may be due to the nature of this specific type of cyberbullying as it does not require an online interaction (in contrary to other types of cyber-victimization). In fact, one does not even have to have an Internet connection in order for rumors to be spread about them.

When asked about the different mediums where cyberbullying took place, the paper-and-pencil survey reported suffering from more cyber-bullying in virtual chat rooms than did online participants. This finding may support the notion that less cyber-victims answering web-based cyberbullying questionnaires. However, we found an opposite result when asked about cyber-victimization via e-mail. It is possible that cyber-victims' coping strategies like avoiding certain web-sites and discussion groups is very different from avoiding e-mail. First, e-mail is personally delivered and in many cases this is done passively and directly to one's smartphone. This is very different than actively logging into different chat rooms or online forums. Second, e-mail is harder to disconnect from as it is a more integral part of school than other online communication services. Third, the effect of the platform itself (e.g., computer, smartphone or paper-and-pencil) mentioned earlier may not have as strong an effect being that e-mail, especially among adolescents, is becoming primarily a phone application while web-based studies are still mainly answered using computers.

This is a preliminary study and has several limitations. Firstly, the sample is small. Second, only the online participants were reimbursed for their participation. This may call online participants' motives into question. Furthermore, the two samples might differ in their socioeconomic status, even though parental occupation was controlled for. Third, while the pen-and-paper and web-based groups were not identically controlled, this fits with the objective of the study, namely, to test for differences between a controlled and an uncontrolled environment.

Given these limitations, this study has important implications. Despite the growing popularity of web-based research on sensitive matters among adolescents, it is still uncertain to what extent it is possible to completely generalize findings regarding depression and cyberbullying from self-selected participants recruited online. We encourage future researchers in the field conducting web-based surveys to acknowledge the restraints of this data collection method. In order to maintain a random sample, surveys completers should not be recruited in a self-selected manner. One option is to continue sampling schools and have as many students of a selected school answer web-based questionnaires from home. This technique may provide many of the advantages of web-based research and strengthen ecological validity.

ACKNOWLEDGMENTS

We would like to thank Mrs. Meytal Grimland for allowing us to use data collected by her for a study on the same topic.

ABSTRACT

Bullying is a major problem in nursing. Baccalaureate nursing students can be exposed to this type of uncivil behaviour on clinical placement in healthcare facilities. Witnessing or experiencing bullying can cause psychological distress in students, negatively affecting their learning and possibly leading them to leave the nursing profession early. Universities have a duty of care to support students during their studies. Clear guidelines and processes

* Corresponding Author's Email: Melanie.birks@jcu.edu.au.

are needed to manage incidents where students have been the victims of bullying while on clinical placement. This paper introduces the ARRCA (Acknowledgement, Recording, Referral, Conciliation and Action) Resolution Model. This model has been developed by the authors in response to increasing numbers of cases where students report bullying. The intention of creating the model was to facilitate a structured investigation of bullying claims, provide each party with the opportunity to reflect on what has occurred and direct an appropriate course of action. Universities, like other modern organisations, must assume zero tolerance to bullying, particularly in relation to students who are vulnerable in the clinical environment. The ARRCA Resolution Model can be applied in other contexts in which conflict or harassment occurs.

Keywords: Bullying; Clinical placement; Conflict resolution; Horizontal violence.

INTRODUCTION

Major changes have occurred in the healthcare environment in the past century. The nursing profession has been influenced and changed by new technology, advances in knowledge, changing scope of practice and diversity in skill mix.

Contemporary health care is complex and dynamic; one thing that has not changed is the culture of bullying in nursing. While the issue exists at all levels of practice, those people who are less equipped to deal with such behaviours – nursing students - are being subjected to bullying while on clinical placement. This paper highlights this unacceptable situation and describes the ARRCA (Acknowledgement, Recording, Referral, Conciliation, and Action) Resolution Model for the management of allegations of bullying.

BACKGROUND

The World Health Organization (Scabstein and Leventhal, 2010) considers bullying to be a major public health issue. It is well documented that nursing has, historically, been littered with episodes of bullying (Cleary et al., 2010; Croft and Cash, 2012; Goldberg, 2008; Hunt and Marini, 2012; Hutchinson, 2013; Johnston et al., 2010; Khadjehturian, 2012). The source of bullying (sometimes called workplace violence, aggression or incivility) in nursing can be other nurses, health professionals or patients and their families (Hutchinson et al., 2013; State of Victoria Government Department of Human Services, 2005). Nursing students are in a vulnerable position within the health care organisational structure, which can set them up to be victims of bullying. Bullying leads to high turnover of staff (ANF, 2009) and ultimately contributes to the shortage of nurses in the workforce (Laschinger et al., 2009).

Workplace bullying can be defined as, “verbal, physical, social or psychological abuse by your employer (or manager), another person or group of people at work” (Australian Human Rights Commission., 2013). A recent Australian study found that almost a third (32%) of nurses had experienced bullying in the workplace from colleagues or supervisors (Farrell and Shafiei, 2012). The consequences of this unacceptable workplace behaviour are distress and injury for the victim. In some cases the effects of bullying may lead to short or long term mental health issues such as anxiety, depression and, in severe cases, post-traumatic stress disorder in the victim (Gregor, 2004).

In Australia, declining funding and staff shortages in the healthcare system have led to more stressful workplaces for nurses and other staff which, in turn, may increase the likelihood of bullying taking place. Hutchinson et al. (2008) suggest specific organisational antecedents for this behaviour, including a culture of tolerance, reward and the misuse of authority, processes and procedures. In nursing, many of these risk factors are legacies of the traditional culture of the profession that has become entrenched and reinforced in a hierarchical health care system. The perpetrators of bullying are often in a position of power or authority over their victim in the organisation or workplace. Unfortunately nurses bully other nurses. Some authors (Duffy, 1995) explain the phenomenon using the 'oppressed group' behaviour theory (Friere, 1972), where the non-dominant group has lowered self-esteem and believes the dominant group is superior. Other authors (Hutchinson et al., 2006) argue that the issue of power differentials in the organisational culture and Foucault's (1977) concept of power provide a better understanding of bullying in nursing.

A glut of studies has investigated this bullying phenomenon in nursing. The Royal College of Nursing (2005) have produced a guide for student nurses to deal with bullying, such is the frequency and seriousness of the problem. Less is known, however, about the effect this behaviour has on nursing students. One study (Thomas and Burk, 2009) analysed nursing students' narratives about clinical placements. In their stories, students described being unwanted, ignored, unfairly blamed or publicly humiliated. Other studies found nursing students were excluded or treated in a dismissive manner on placements (Anthony and Yastik, 2011; Hutchinson et al., 2010). In one Australian study of 152 nursing students, 57% reported having seen or experienced horizontal violence while on clinical placement (Curtis et al., 2007). While this number is high, there is much anecdotal evidence to suggest that the true figure is higher and that much of this behaviour during clinical placements goes unreported.

The Nature of the Problem

Workplace incivility and aggression are known to harm the social, emotional and physical wellbeing of the student and, consequently, reduce the quality of the clinical placement (Siggins Miller Consultants, 2012). Nursing academics and managers of clinical placements are well aware of the consequences of bullying. The authors of this paper have first-hand experience of working with students whose exposure to bullying has led them to rethink their nursing career. Universities hand over the duty of care and responsibility for students to healthcare facilities in the process of providing clinical placements. Health care facilities are legally bound to provide students with a safe working environment in the same way that they do so for paid staff. Although the student is seen as a member of the facility in such circumstances, the university still owes the student a duty of care and is thus obligated to minimise the risk of students being exposed to bullying and to effectively manage situations once identified.

Bullying of students that takes place externally to a university is more challenging to manage than that which happens within the university. The student nurse may not know whether to go to staff at the university or within the clinical environment with a complaint. Also, the student will often be unaware of the appropriate channels to go through to get help. They might experience feelings of fear, particularly of retaliation, if they take action by reporting this unacceptable behaviour. In the following section a strategy is outlined for managing reports of bullying of students on clinical placement. The ARCCA Resolution Model

is a framework that represents a responsible and accountable approach to managing the potentially complex and difficult issues surrounding bullying of nursing student in health care facilities.

The ARCCA Resolution Model

The ARCCA Resolution Model has been developed to manage situations where a nursing student has reported bullying. Use of the model promotes clarity and affords each party the opportunity to reflect on what has occurred, while identifying an appropriate course of action with which to move forward. This approach enables organisations to meet their obligations to recognise, acknowledge and investigate issues of bullying, while directing an appropriate course of action that ensures fair treatment for all affected parties.

The strategy consists of the phases outlined in Figure 1.

Figure 1. The ARCCA Resolution Model.

The phases of the ARCCA Resolution Model can proceed in a linear fashion but may also occur concurrently. Recording, for example, is undertaken throughout the entire process and discussions towards conciliation will inevitably commence early and continue throughout. As such, this model provides a functional and flexible framework for use by clinical placement managers and academics.

Acknowledgment refers to the need to recognise, either verbally, in writing, or in both forms, that a complaint has been received. Acknowledgement of a complaint does not imply agreement that there has been an incident of harassment or bullying, but provides the complainant with confirmation that the nature of the complaint is understood and will be investigated accordingly. Both the university and health care facility should provide acknowledgement that a complaint has been received.

Acceptance of the complaint requires *recording*, in accordance with the policy of the organisation. This process might involve incident reporting or the recording of the incident on a computerised risk management program. The student should be encouraged to prepare a

statement outlining their recollection of events surrounding the complaint as soon as possible. Where breach of confidentiality is not a concern, documentation should be shared with all parties concerned to promote transparency of the process.

Critically, from an early stage, efforts must be made to ensure prompt and appropriate *referral* of all parties involved in the issue to counselling and support services. Most universities and health care facilities have counselling and support services available for students and staff and efforts should be made to arrange for timely intervention for affected individuals. It may be necessary for access to these services to be negotiated on behalf of the staff and students.

As soon as practicable, a *conciliation* discussion should be arranged to enable all relevant facts to be gathered. Conciliation should involve the student, university representative, facility representative and the facilitator and/or staff member involved in the reported event. Provision should also be made for individuals to bring along support persons should they feel the need to do so. The intent of discussion is to promote transparency and inclusivity in the management of an allegation of harassment or bullying. The process is therefore both investigative and conciliatory, but should never be allowed to become adversarial or accusatory.

The final phase of the model is to identify an appropriate course of *action*. It is possible that the process of conciliation may resolve any issues that resulted from confusion or miscommunication and all that will be required is monitoring of the situation. In other circumstances, as determined by the evidence gathered, it may be necessary to intervene further. In such cases, one of three courses of action may be proposed:

1. Parties are referred for further mediation
2. Student performance issues are identified and addressed
3. A formal complaint is lodged with the facility

Whatever the course of action determined, a decision will need to be made in respect of whether the student should return to the clinical environment in which the situation arose. Whether the student should be placed back in that environment, in another setting or indeed, not at all, is first and foremost determined through establishing what is in the best interest of the patients, the student and the staff. Complete withdrawal of the student from placement may be essential when there are concerns about the ability of the student to practise safely. Similarly, where a particular environment is considered unsafe for the student, alternative placement arrangements may need to be made.

A summary of the responsibilities of each party in the use of the ARCCA Resolution Model is presented in Table 1.

Application of the AARCA Resolution Model

In order to understand the application of the ARCCA Resolution Model in practice, we present a hypothetical case study. Box 1 presents a situation that is a composite of many that the authors have seen over recent years.

Table 1. Summary of responsibilities of each party in the ARCCA Resolution Model

Phase	Student	University	Health care facility
1.Acknowledgment	Receives written or verbal acknowledgement	Provides written or verbal acknowledgement	Provides written or verbal acknowledgement
2.Recording	Documents the events	Documents reported events in accordance with university policy	Documents reported events in accordance with institutional policy and provides these to the university as appropriate
3.Referral	Student is provided with information about, or direct referral to, support services	Provides student and staff with written or verbal referral to support services and/or facilitates access as required	Provides student and staff with written or verbal referral support services and/or facilitates access as required
4.Conciliation	Attends conciliation meeting	Attends conciliation meeting and facilitates the discussion	Attends conciliation discussion and makes relevant staff available
5.Action	Participates in mediation as appropriate Complies with plan to address any identified performance issues Provides evidence as required for formal complaint processes if applicable	Arranges and participates in mediation as appropriate Prepares plan to address any identified student performance issues Facilitates formal complaint process as required Arranges alternative placement for student if necessary	Participates in mediation as appropriate Assists with the implementation of any plan to address any identified student performance issues Responds to formal complaint when received in accordance with institutional policy and prevailing law

Box 1. Case Study**Kellie's story**

Kellie is a third-year nursing student who is attending a regional hospital for an acute care clinical placement. The university has received a telephone call from Kellie reporting bullying by nurses at the hospital. The clinical facilitator has also rung advising that Kellie has been asked to leave the facility. The manager of the unit where Kellie has been placed has raised concerns about her performance and attitude over the preceding three weeks of her placement. The clinical facilitator informs the university's clinical placement manager that the student is alleging that she has been bullied by the unit manager and two other staff members in the facility.

In the hypothetical case study provided, it would be tempting for the recipient of the complaint of bullying to simply assume that Kellie is making the allegation in defence of questions raised about her performance. It is important for the clinical placement manager or academic who received the complaint to suspend judgement and treat the matter impartially. Unfortunately, students can also behave in a less than appropriate manner while on clinical placement (Anthony and Yastik, 2011). When this occurs the student may take a defensive stance and respond to negative feedback from the facility or facilitator by alleging that they have been subjected to harassment or bullying. The clinical placement manager or academic is therefore tasked with determining whether the student has in fact been bullied and unfairly treated or is simply raising a defence after claims of poor performance.

An investigation must be undertaken before making any assumptions or decisions about action. The clinical placement manager or academic who received the complaint should suspend judgement and treat the matter impartially. Kellie needs to be given clear *acknowledgement* of the complaint and an explanation of the process that will be followed. Her options in respect of any other courses of action should also be explained to Kellie. The clinical placement manager or academic should seek to make contact with the facility to advise them that a complaint has been made and to explain the processes that will be followed in investigating and managing the situation.

Recording of all events from the time of the first meeting with Kellie is important to ensure that all facts are documented contemporaneously. As much information as possible should be gathered about the circumstances leading to the complaint being made. Kelly should be encouraged to document events in accordance with her recollection. The facilitator should also be asked to provide a report of Kelly's performance. The manager and identified staff of the unit where Kelly was placed should also be asked to provide details about the concerns raised regarding Kellie's performance. Other evidence such as previous clinical reports relating to this student should also be gathered. Equally, it is important that all such documentation and subsequent correspondence is retained in a secure location. The health care facility may request copies of documentation and where corporate or personnel confidences are not at risk, these requests should be complied with.

Regardless of how the student may present, *referral* to support services should be arranged. Attention should also be paid to others involved in the situation. The manager and staff of the unit who have been accused of bullying are likely to be distressed. The health service has an obligation to ensure their wellbeing but the staff of the university must also be mindful of the impact that the allegation is likely to be having on these individuals. Furthermore the clinical facilitator/preceptor involved should be counselled about this situation as they may be feeling compromised, particularly if they are seconded to the role from the facility.

The *conciliation* discussion should be arranged as soon as possible and the student, their support person, the clinical facilitator, manager and staff of the unit should be given the opportunity to attend. Whether the clinical placement manager or academic manages mediation, or an external facilitator is brought in for this purpose, the forum should commence with the establishment of ground rules for how the session will proceed. Ensuring that all those in attendance are aware of appropriate behaviour from the outset can prevent problems as the conciliation discussions progress. Parties should be encouraged to deal in facts and objective information. Emotions should be acknowledged, but the focus must remain on finding an appropriate solution. From the perspective of the education provider and healthcare facility,

safety and wellbeing of patients, students and staff are paramount. This should remain at the forefront when seeking to identify a satisfactory outcome.

As can be seen from the case study example presented, the process provides each party with an insight into the others' perspectives. Kellie's performance in the clinical environment was not as expected for a third year student in that setting. The staff lacked skills in conveying to her their expectations and how best to address the issues at hand. A formal complaint was not lodged as each person involved developed a greater understanding of the reasons that underpinned the behaviour of others. Rather, the **action** taken in this instance was the development and implementation of a clinical learning contract to address Kellie's learning needs and deficits and she returned to the clinical placement with a greater level of support.

DISCUSSION

All organisations must promote a zero tolerance position on bullying, regardless of the environment (Queensland Nurses' Union, 2012). Universities placing students with external institutions must demonstrate that complaints of bullying will be taken seriously (Queensland Government, 2011) and provide a transparent management process. The objectives of the ARCA Resolution Model are to establish a procedure that enables the student to report such occurrences in a safe and understanding environment; ensure that these events are thoroughly investigated and documented; provide all stakeholders with the opportunity to respond from all perspectives of interaction in the clinical environment and follow an appropriate course of action. The success of this strategy relies on the ability of those that apply it to do so with objectivity and sensitivity. Nevertheless, as with any framework or guideline for practice, there are inherent advantages and disadvantages (Box 2). Awareness of these limitations enables the clinical placement manager or academic to employ the model to promote the best outcome.

Nursing is a demanding profession and the additional stress that results from the threat of bullying in the clinical environment has implications for the retention of nurses in the workforce (Clarke et al., 2012). Students have the right to be placed in a safe environment and to be confident that any issue that does arise will be handled appropriately. Bullying can manifest in many ways and often these can be subtle and disregarded. Conversely, not all behaviours that a student may respond to negatively can justifiably be labelled as bullying (Cleary et al., 2010). When such allegations are raised there is potential for confusion, further conflict and damage to relationships. The focus must therefore be on establishing the facts of the matter and ensuring a swift resolution. The ARCA Resolution Model is designed to facilitate such outcomes.

An issue of student bullying on clinical placement may be raised by the student themselves, the clinical facilitator or others who witness unacceptable behaviour, such as other students. Often these events are not reported at all where students fear reprisals (Cleary et al., 2010). This is particularly the case if they have time yet to serve in that clinical environment. Sadly, underreporting may also result from a tolerance amongst students who believe that it is just something they are expected to deal with in a nursing environment and that making a complaint would be a futile exercise.

Box 2. Advantages and disadvantages of the ARCCA Resolution Model

Advantages
Facilitates information sharing in a controlled environment
Increases individual self-awareness, inclusive of student, facilitator, facility representative and university representative
Allows insight from various sources and perspectives
Provides an avenue for coaching and mentoring for students, facilitators and facility staff resulting in improved performance
Alters the culture of incivility in nursing globally, by acting locally
Nursing students are taught not to accept bullying behaviour in the workplace
Future nurses gain experience of appropriate processes to follow when faced with this type of conflict and behaviour
Provides an avenue for behavioural management for all parties
Enables nurses already in practice an opportunity to self-reflect, modifying the attitude of self and those around them
Reduces attrition of nursing students by creating access to processes to manage bullying behaviour
Reduces the number of clinical educators lost from field work
Disadvantages
Participants have conflicting perspectives
Can be emotionally overwhelming and stressful for all individuals involved
If not managed well, has the potential to be an explosive conflict situation
Can be time-consuming
Organising availability of parties and compliance with attendance can be difficult

It is important to ensure that during the clinical placement briefing students are made aware of behaviours that are unacceptable and are provided with clear information about the reporting process should they have any concerns about their off-campus experience. Specific teaching strategies should also be incorporated into the curriculum to help build student resilience to assist them to deal with issues in the clinical setting and following graduation. The clinical facilitator should also be briefed about the university's policies and processes in respect of bullying and the importance of ensuring that all allegations are reported, regardless of how trivial they may be seem.

Irrespective of when or how a report of bullying comes to light, the situation must be approached sensitively and without prejudice. Each situation of bullying is different and should be considered carefully and individually to understand the specific circumstances. Emotions usually run high in cases where people feel that they have been treated badly and this has the potential to both inflame and cloud the issue. Both the university and the health care facility must be careful not to appear dismissive about any complaint made and recognise the impact that such a complaint has for all of those people involved. The ARCCA Resolution Model outlines a process that is practical and accessible to the student and others directly affected by the allegation.

CONCLUSION

Though the outcomes may vary, the aim of the ARCCA Resolution Model is to manage and ultimately change the culture of bullying behaviour that continues to exist in the healthcare industry. The use of a student-focused approach during clinical placement enables health care facilities and universities to ensure that nursing students on clinical placement are supported and provided with a safe environment. In the case of the bullied nursing student, application of the ARCCA Resolution Model will ensure that all parties take appropriate action. The outcome of this approach will be that students will no longer feel fearful of reporting bullying behaviour that occurs during their clinical placement. Nursing as a profession has the power to change past indoctrinated incivility. By empowering nursing students to report unacceptable workplace behaviours, universities and nursing students have the ability to change the culture of nursing into a positive working environment that facilitates lifelong learning. The AARCA Resolution Model is a generic framework for resolution of allegations of bullying. This model has application in both nursing and the healthcare environment more broadly and, potentially, in other industries where collegial incivility, harassment or conflict is an issue.

Chapter 108

OCCUPATIONAL STRESS AS AN ANTECEDENT OF WORKPLACE BULLYING IN THE EDUCATION SECTOR

²Universidad de Sevilla, Spain

ABSTRACT

The main objective of this chapter is to analyze the relationship between occupational stress and workplace bullying in the educational sector. The data used for this research is obtained from the 5th European Working Conditions Survey, conducted in 2010 by the *European Foundation for the Improvement of Living and Working Conditions*. Given the objective of this work, it is collected a sub-sample of 261 education employees that includes a part of the International Standard Classification of Occupations (ISCO-08) sub-group 23: teaching professionals. In order to test the research model and hypotheses this study relies on the use of partial least squares (PLS-SEM), a variance-based structural equation modeling method. The study describes a workplace bullying prevalence rate of 4.4% among education employees. This work summarizes an array of outcomes with the aim of proposing, in general, that workplace bullying may be reduced by limiting job demands and increasing job resources.

1. WORKPLACE BULLYING, A HETEROGENEOUS PHENOMENON

The workplace bullying has a detrimental effect on both individuals and organizations, e.g., managerial costs and turnover escalate and productivity declines (Gonzalez-Mulé et al., 2013). Other economic consequences, with a significant negative influence on profits, can sometimes

* Corresponding Author's Email: ariza@uloyola.es.

† Corresponding Email: alleal@uloyola.es.

‡ Corresponding Email: aleal@us.es.

be difficult to measure and hard to define clearly: e.g., quality reduction, negative impacts on the organization's reputation, the escalation of mistakes and absenteeism, and the deterioration of relationships with customers due to a lack of attention paid to their objectives and commitments (Gumbus and Lyos, 2011). This statement becomes even more significant for those organizations that are mainly composed by employees who provide particular assistance to citizens in a close and direct way, such as teachers. Teaching presents certain peculiarities nowadays –loss of social status, direct contact with customers who do not always wish to receive the service, rivalry and competition among colleagues, etc.– that generate a suitable breeding ground for the development and propagation of bullying. Bullying has become a true pandemic of harmful effects, which are accentuated by the greater vulnerability of many teachers who are subdued to the tyranny that the labor market dictates in a context of crisis and job instability. More precisely, this chapter is drawn up in accordance with former studies that have shed light on how workplace bullying among teachers has become a generalized phenomenon in the academic context. In this sense, some authors indicate the highest prevalence of workplace bullying in social and health sectors, public administration, and education (Zapf et al., 2003).

Scientific literature has explored bullying via different conceptions (Aquino and Lamertz, 2004): intimidation, harassment, victimization, aggression, emotional abuse, psychological harassment, or mistreatment at workplace. Despite the proliferation of definitions, there seems to be a common consent on the fact that bullying could be defined in terms of the intentionality of the behavior, its frequency (e.g., weekly) or duration (e.g., about six months), the targets' reaction(s) toward the situation, a perceived imbalance and misuse of power between perpetrator and target, inadequate support, and the target's inability to defend him/herself from such predicaments (Einarsen et al., 2011; Einarsen et al., 2003; Einarsen, 1999; Einarsen, 1996), having to face negative and constant social interactions (Einarsen et al., 2011), physical or verbal badgering, insults remarks (Einarsen et al., 2003), and intense pressure (Sandmark, 2009), among others.

With respect to the extent of its manifestation, there is a strong disagreement regarding bullying prevalence: from 4% to 5% in Northern European Countries (Nielsen et al., 2012; Nielsen et al., 2009) versus 15% in Southern European nations (Giorgi et al., 2011). Certain factors, such as cultural characteristics and societal changes, may contribute to explain variations in prevalence rates. Issues related to research methodology ought to be taken into consideration as well (Nielsen et al., 2009): studies on workplace bullying are performed utilizing an array of diverse measurement methods, instruments, and study designs (Agervold, 2007; Zapf et al., 2003), beyond what it seems reasonable to consider some methodological procedures as influences on observed prevalence rates (Nielsen et al., 2010). As will be shown in subsequent paragraphs, statistics paint a bleak picture of teachers' exposure to hostility, mostly because bullying at work, in the context of educational institutions, also includes interactions between co-workers, school administrators, students, parents, and others.

Although definitions have a propensity to converge persistence and duration as the key construct of the phenomenon, it is further substantiated in the present chapter that workplace bullying has a strong psychological component for its materialization. In fact, an essential condition of bullying is that the act itself has to be perceived by the target as a hostile circumstance (Einarsen, 1999; Einarsen and Skogstad, 1996). From this point of view, the pernicious effects of workplace bullying (anxiety, depression, absenteeism, lack of organizational commitment, etc.) will be externalized with a greater magnitude at the moment

the target perceives this objectionable situation, independently of the persistence or duration of the bullying act. Adopting this focus and taking into account that the academic environment has a number of organizational and work features that increase the likelihood of hostile interpersonal behaviors (Twale and De Luca, 2008; Neuman and Baron, 2003), the main objective of this research is to analyze the effect of the work stress-motivation relationship on the workplace bullying from the perspective of the Job Demands-Resources (JD-R) model (Demerouti and Bakker, 2011), in such a way that it is possible to anticipate the teachers' degree of well-being and job performance.

2. WORKPLACE BULLYING AMONG TEACHERS

The studies on harassment began in the decade of the eighties at the Nordic countries, as a result of the innovative investigations on school bullying at that time (Leymann, 1990; Matthiesen, Raknes and Røkkum, 1989). Precisely, Heinz Leymann (1990), a German psychiatrist, is currently considered as the pioneer in this type of works (Rayner et al., 2002). His initial interest in bullying was subsequently extended to the harassment at work (that he labeled "mobbing"), as he identified similar dynamics in adult patients (Lutgen-Sandvik, Tracy and Alberts, 2007).

Despite its origin, linked to the educational environment, and that occupations such as teaching have been suggested to be particularly susceptible to bullying (Randall, 2001), research on the workplace bullying experienced by teachers is not sufficiently developed, something that is confirmed by the significant prevalence rates obtained by different studies. Therefore, Keashly and Neuman (2010) carry out a review of the works on bullying at the University context and conclude that the rates of bullying seem relatively high when compared to those noted in the general population, which range from 2% to 5% in Scandinavian countries, 10% to 20% in the UK, and 10% to 14% in the United States (Keashly and Jagatic, 2010; Rayner and Cooper, 2006). Moreover, there is evidence of the high incidence of bullying within the education sector in many countries: Australia (McCarthy et al., 2003; Vickers, 2001), Finland (Bjorkqvist et al., 1994), the Netherlands (Hubert and van Veldhoven, 2001), the UK (Lewis, 2003; Hoel and Cooper, 2000), the USA (Price, 1995). Furthermore, it has been demonstrated that school teachers in China (McCormack et al., 2006), Ireland (O'Moore et al., 2003), the UK (Edelmann and Woodall, 1997; NASUWT, 1996) and the USA (Blase and Blase, 2003) have been targets of workplace bullying. In some countries, such as Turkey, research shows that 50% of the Turkish primary school teachers had experienced bullying (Cemaloğlu, 2007).

But, what is this higher incidence of bullying in the education sector due to? The causes must be sought in different areas:

At a *contextual level*, the teaching profession has experienced a deterioration of its traditional social status and prestige in western countries, which has resulted in a lower authority that converts teachers in victims much more vulnerable to potential bullying situations. This loss of credit and reputation comes from the establishment of post-materialist values in many of these societies, values that attach greater importance to individualism, independence or freedom, in contrast to more traditional ones like order, obedience, hierarchy, power and respect for authority (Inglehart and Welzel, 2005; Inglehart, 2003; Inglehart, 1997).

This situation of greater fragility has been accentuated by the severe economic crisis suffered by the European economy from several years ago and that has meant important budget cuts in sectors that are so critical to social welfare such as healthcare and education.

At the *Organizational level*, several investigations reveal that certain innate characteristics to the teaching profession and to the work environment in which this one develops, generate an ecosystem favorable to the arise of attitudes and behaviors that can derive in workplace bullying. In this way, in the academic context, ideological confrontation, professional rivalry, personal animosity, power struggles and antipathies between colleagues, etc., are more likely to occur. This conflict is emphasized by the deep network of social relations that are manifested in this type of institutions (some of which may play a pivotal role for the promotion and development of the teaching career), to the extent that some authors consider the quality of personal relationships as an important factor in retention of faculty (Norman et al., 2006). According to Korkmaz and Cemaloğlu (2010), workplace bullying is especially problematic when it occurs in places where social relations are dense, such as in educational institutions. In this sense, Keashly and Neuman (2010) warn that academia may be a particularly vulnerable setting for such persistent aggressions as a result of tenure, which has faculty and some staff in very long-term relationships with one another. To this must be added that the deeply rooted value of academic freedom may cause an adverse effect which hinders the authorities interference within the teachers' interpersonal disputes, even when circumstances so advise it in order to gain in transparency. For instance, at the departmental level, where people have "issues" with each other and are often in competition for scarce resources (money, equipment, space, power, high-caliber students, etc.), hidden agendas can abound (Higgerson and Joyce, 2007). This circumstance allows conflicts to escalate, resulting in a toxic climate and an increased likelihood of aggression and bullying (Keashly and Neuman, 2010). This atmosphere of labor relations deterioration within the education sector is even more intense at the University level, especially in those universities where a market-orientation philosophy is deeply imbued and, therefore, where the value of competitiveness is something not only accepted but also promoted by academic authorities. This competitiveness, encouraged by accreditation processes, which in turn determine the access to increasingly scarce jobs and the promotion on the hierarchical scale, creates a scenario conducive to the sprout of bullying actions. This issue is addressed by Zabrodska and Kveton (2013) who indicate that newly reformed neoliberal universities, with their micro-management of ever-increasing productivity, competitiveness, and individualization, create conditions that incite workplace bullying and other form of employee abuse. The competitiveness of the academic context is accompanied by a strong sense of hierarchy and high degrees of regulation and bureaucracy. As a result, some of the core causes of inappropriate behavior in academia are institutional norms, organizational structures, academic culture and systemic change (Twale and De Luca, (2008). In the same line, Hubert and van Veldhoven (2001) sustain that a possible explanation for the relatively high rate of workplace bullying among schoolteachers lies in the nature of teacher output; specifically, its quality and quantity are difficult to measure, resulting in a high emphasis being placed on interpersonal relationships with both colleagues and superiors in performance appraisals. In a similar way, both Keashly and Neuman (2010), and Tigrel and Kokolan (2009), consider that other potential bullying drivers are the high performance expectations typical of academia that are combined with subjective and vague criteria for performance evaluation. The ambiguity of evaluation processes may cause a feeling of injustice and, thus, a greater perception of harassment, especially because superiors have greater

opportunities to make decisions in an arbitrary manner that negatively influence their subordinates' lives. Even when evaluators operate with good intentions, commenting the performance of colleagues belonging to other fields of knowledge is complicated and contentious, and can generate a sense of injustice, real or imagined. It should not be forgotten that bullying in the educational environment, is possibly more indirect (prevent access to key resources, undermine the authority, damage the professional prestige, etc.) than direct (threats, physical assaults, insults...). Therefore, it is a subtler, less detectable, even questionable harassment. Within the academic culture of reasoned discussion and debate, such behaviors can be justified by the bully as normative, that is, part of the "cut and thrust" of academic discourse (Nelson and Lambert, 2001).

Finally, at the *individual level*, many academic workers aspire to work in a highly vocational profession, in which they have deposited great expectations about the level of autonomy available in their work-related activities, recognition, participation opportunities, power and influence, a strong sense of entitlement, etc. Accessing to the profession makes many of them to face a very different reality: academic hierarchies more rigid than expected, excessive bureaucracy, overexertion in coordination with the rest of the team mates (and even of subjugation to the dictates of the more veterans, that limits the possibilities of contributing with their own criterion), irregular distribution of the work time, that combines periods of overload, which generate conflict with personal life, with others of less activity, etc. When expectations are not matched, it may result in a breach of the psychological contract and the emergence of feelings of frustration, disappointment or injustice that, ultimately, and given the subjectivity component associated with the phenomenon investigated, may result in a greater sense of bullying among teachers.

The fact that workplace bullying is a problem with a higher prevalence among teachers than in other sectors seems to be a fact as unquestionable as worrying. Studying in depth this matter turns out to be critical, since teachers are erected in models, becoming the driving belt of values and conducts for the future generations. It is sure that the quality of service and the type of messages transmitted to students is affected by the teacher's level of well-being. Therefore, it is easy to imagine how complicated it must be to teach and transmit values when one feels harassed at its own workplace. Aware of this fact, this chapter deals with the problem of teachers' workplace bullying from a novel and little investigated approach, the Job Demands-Resources (JD-R) model.

The hypotheses that we will test are the following (see Figure 1):

Hypothesis 1. Certain work demands that teachers have to face will result in work stress.

Hypothesis 2. The resources available to teachers act as predictors of their motivation in the workplace.

Hypothesis 3. Resources can soften the impact of the demands on work-related stress, mitigating its harmful effects

Hypothesis 4. Work resources take on greater importance and have greater impact on motivation when demands are high

Hypothesis 5. Stress generates bullying sensation

Hypothesis 6. The teacher's degree of motivation contributes to reduce workplace bullying.

Figure 1. Research model and hypotheses

3. METHOD

3.1. Data Collection and Sample

The data utilized for this research is obtained from the 5th European Working Conditions Survey, conducted in 2010 by the *European Foundation for the Improvement of Living and Working Conditions*. This survey provides insight related to the working environment and employment situation of the 27 EU Member States, as well as Turkey, Croatia, Norway, Macedonia, Montenegro, Albania, and Kosovo. The target population under study comprises those aged 15 years and over (16 and over for the case of Spain, the UK, and Norway), employed and residing in the country being surveyed. The sample is a multi-stage and stratified random sample. The total number of interviews is over 43,000, being gathered in 2010. The study denotes a prevalence workplace-bullying rate of 4.4 % among teachers. Given the objective of this work, it is collected a sub-sample of 261 education employees that includes a part of the International Standard Classification of Occupations (ISCO-08) sub-group 23: teaching professionals; 48.7% of these teachers report having experienced workplace bullying (N=127), while 51.3% indicate not considering themselves as bullied at work (N=134).

The sample comprised 211 teachers in government schools (80.8%) and 50 teachers in non-government schools (19.2%). It covered 181 females (69.3 per cent) and 80 males (30.7 per cent). There were 95 female teachers (74.8 per cent) and 32 male teachers (25.2 per cent) between workplace bullying participants while there were 86 female teachers (64.2 per cent) and 48 male teachers (35.8 per cent) between non-workplace bullying professionals. The average age of the participants was 41.7 years (standard deviation (SD) = 10.8 years). The average tenure was 12.3 years (SD = 10.3). For workplace bullying teachers, the average age

was 43.5 years ($SD = 10.6$), and the average tenure was 12.5 years ($SD = 10.1$). For non-workplace bullying teachers, the average age was 40.1 years ($SD = 10.9$), and the average tenure was 12.2 years ($SD = 10.6$).

3.2. Measures

The dependent variable of this analysis is bullying at work. Respondents are asked to answer just one question on their individual perception regarding the following matter: *Over the past 12 months, during the course of your work, have you been subjected to bullying/harassment?*

Bullied teachers are codified as 1, while those who claim not to have felt bullied are codified as 0. Two different approaches are mainly used in bullying research when questionnaires are implemented: the self-labeling and the operational approach; the limitations and advantages of these methods are discussed in Nielsen et al. (2011).

Workplace bullying is pondered in this work as a complex phenomenon that arises due to the dynamic interaction of work stress and motivation. Taking into account the Job Demands-Resources model, it is arranged two sets of independent variables grouped into two categories: Job Demands factors and Job Resources factors. The codes and classification of explanatory variables are presented below:

Job Demands: D1. Work overload (0: No; 1: Yes), D2. Working to tight deadlines (0: No; 1: Yes), D3. Work on weekends (0: No; 1: Yes), D4. Monotonous tasks (0: No; 1: Yes), D5. Complex tasks (0: No; 1: Yes), D6. Rotating tasks (0: No; 1: Yes), D7. Learning new things (0: No; 1: Yes), D8. You know what is expected of you at work (role ambiguity) (0: Yes; 1: No), D9. Your job involves tasks that are in conflict with your personal values (role conflict) (0: No; 1: Yes), D10. High emotional demand of the work (0: No; 1: Yes), D11. Handling angry clients (0: No; 1: Yes).

Job Resources: R1. Autonomy over the content of the work (0: No; 1: Yes), R2. Capacity to decide the timetable (0: No; 1: Yes), R3. Colleagues support (0: No; 1: Yes), R4. Supervisor support (0: No; 1: Yes), R5. Feeling of work well done (0: No; 1: Yes), R6. Feeling of doing useful work (0: No; 1: Yes), R7. Supervisor feedback (0: No; 1: Yes), R8. Expectation of career advancement (0: No; 1: Yes), R9. Organizational commitment (0: No; 1: Yes), R10. Training paid by the employer (0: No; 1: Yes), R11. Possibility of choosing the partners (0: No; 1: Yes), R12. Payment satisfaction (0: No; 1: Yes).

3.3. Data Analysis

In order to test the research model and hypotheses this study relies on the use of partial least squares (PLS-SEM), a variance-based structural equation modeling method. PLS is a suitable technique for use in this study due to the following reasons (Roldán and Sánchez-Franco, 2012): (1) the sample ($n = 261$ cases) is small; (2) the study is focused on the prediction of the dependent variables; and (3) the research model is considerably complex with regard to the type of relationships in the hypotheses. In order to perform the measurement and structural model analysis we used the SmartPLS software (Ringle, Wende and Will, 2005).

4. RESULTS

A PLS model is assessed and interpreted in two phases: (1) the evaluation of the reliability and validity of the measurement model (outer model), and (2) the evaluation of the structural model (inner model). This sequence guarantees that the constructs' measures are valid and reliable before attempting to obtain conclusions with regard to the relationships between constructs (Roldán and Sánchez-Franco, 2012).

Table 1. Measurement model

Construct/ indicator	VIF	Weight	Loading	Composite reliability (CR)	Average variance extracted (AVE)
Workplace Bullying (reflective construct)				1	1
WB			1		
Stress (reflective construct)				1	1
S			1		
Motivation (reflective construct)				1	1
M			1		
Job Demands (formative construct)				N.A.	N.A.
<i>D1. Work overload</i>	1.332	0.331			
<i>D2. Working to tight deadlines</i>	1.010	-0.157			
<i>D3. Work on weekends</i>	1.331	0.197			
<i>D4. Monotonous tasks</i>	1.114	0.201			
<i>D5. Complex tasks</i>	1.120	0.034			
<i>D6. Rotating tasks</i>	1.054	-0.031			
<i>D7. Learning new things</i>	1.067	0.047			
<i>D8. Role ambiguity</i>	1.030	0.167			
<i>D9. Role conflict</i>	1.029	0.322			
<i>D10. Emotional demand of the work</i>	1.020	0.235			
<i>D11. Handling angry clients</i>	1.075	0.542			
Job Resources (formative construct)				N.A.	N.A.
<i>R1. Autonomy over the content of the work</i>	1.053	-0.182			
<i>R2. Capacity to decide the timetable</i>	1.002	-0.032			
<i>R3. Colleagues support</i>	2.175	0.107			

Construct/ indicator	VIF	Weight	Loading	Composite reliability (CR)	Average variance extracted (AVE)
R4. Supervisor support	2.828	-0.023			
R5. Feeling of work well done	1.185	0.065			
R6. Feeling of doing useful work	1.165	-0.109			
R7. Supervisor feedback	1.778	0.441			
R8. Expectation of career advancement	1.212	0.146			
R9. Organizational commitment	1.333	0.097			
R10. Training paid for by the employer	1.004	0.044			
R11. Possibility of choosing the partners	1.208	0.288			
R12. Payment satisfaction	1.062	0.595			

N.A.: Not applicable.

4.1. Measurement Model

The assessment of formative measurement models involves the test for potential multicollinearity between items and the analysis of weights (Henseler et al., 2009). We used the IBM-SPSS software to perform a collinearity test. The maximum variance inflation factor (VIF) values for the manifest variables that shape the formative constructs JD and JR are well below the threshold of 3.3 (Diamantopoulos and Siguaw, 2006) (Table 1). On the other hand, weights provide information about how each item contributes to the construct measurement. Hence, they give rise to a ranking of these indicators according to their contribution (Henseler et al., 2009). Table 1 reveals that indicators D11 (*handling angry clients*; 0.542), D1 (*work overload*; 0.331), D9 (*role conflict*; 0.322), D10 (*emotional demand*; 0.235), D4 (*monotonous tasks*; 0.201) and D3 (*work on weekends*; 0.197) represent the most significant dimensions in the composition of the JD construct. R12 (*payment satisfaction*; 0.595), R7 (*supervisor feedback*; 0.441), R11 (*possibility of choosing the partners*; 0.288), R8 (*expectation of career advancement*; 0.146) and R3 (*colleagues support*; 0.107) represent in turn the most significant items while measuring the JR construct.

Evaluating reflective measurement models comprise assessing its reliability and validity. The results show that the measurement model meets all common requirements. First, all the reflective indicators are reliable because all standardized loadings surpass the 0.7 level (Table 1). Consequently, the individual item reliability is adequate (Carmines and Zeller, 1979). Second, all the reflective constructs –Workplace Bullying (WB), Stress (S) and Motivation (M)– meet the construct reliability requirement, since their composite reliabilities (ρ_c) are greater than 0.7 (Nunnally and Bernstein, 1994) (Table 1). In addition, these latent variables achieve convergent validity because their average variance extracted (AVE) measures are greater than 0.5 (Fornell and Larcker, 1981) (Table 1). Finally, all variables reach discriminant

validity. Confirmation of this validity comes from the comparison of the square root of AVE versus reflective latent variables correlations (Table 2). For satisfactory discriminant validity, the diagonal elements should be significantly greater than the off-diagonal elements in the corresponding rows and columns (Roldán and Sánchez-Franco, 2012).

Table 2. Discriminant validity

	WB	S	JD	JR	M
WB	1	0	0	0	0
S	0.2548	1	0	0	0
JD	0.3677	0.3456	N.A.	0	0
JR	-0.2683	-0.197	-0.296	N.A.	0
M	-0.2292	-0.0468	-0.3003	0.4688	1

Diagonal elements (bold) are the square root of variance shared between the constructs and their measures (AVE).

Off-diagonal elements are the correlations among constructs.

For discriminant validity, the diagonal elements should be larger than the off-diagonal elements.

Note: N.A.: not applicable.

4.2. Structural Model

Table 3 shows the explained variance (R^2) in the endogenous variables and the path coefficients for the hypotheses posited in the model under study. Bootstrapping (5,000 resamples) provides t-values that allow the evaluation of the statistical significance of the relationships included in the research model (Roldán and Sánchez-Franco, 2012). Therefore, for the current data sample H1, H2, H5 and H6 have proven to be significant, whereas we have failed to prove significance for H3 and H4 (Figure 2).

Figure 2. Structural model results.

Table 3. Structural Model Results

Relationships	Significance
	$R^2_{\text{Stress}} = 0.129$
	$R^2_{\text{Motivation}} = 0.248$
	$R^2_{\text{Workplace Bullying}} = 0.112$
H1: JD→S	0.315* (2.118)
H2: JD→M	-0.177 ^{ns} (1.274)
H3: JR→M	0.416*** (4.167)
H4: JR→S	-0.104 ^{ns} (0.739)
H5: S→WB	0.245*** (4.191)
H6: M→WB	-0.218*** (4.011)

t values in parentheses.

*** $p < 0.001$; ** $p < 0.01$; * $p < 0.05$; ns: not significant (based on (4999), one-tailed test) $t(0.05, 4999) = 1.645$; $T(0.01, 4999) = 2.327$; $t(0.001, 4999) = 3.092$.

5. DISCUSSION

Bullying is a dangerous toxic gas that, similarly to the firedamp in mines, silently expands throughout the entire organization. The problem is that once it is detected it could be late, and their effects irreversible for the firm's health. Following to Giorgi and Majer (2009), once a workplace has an entrenched pattern of negative interaction, it can be difficult if not impossible to disrupt. For this reason, the advances in terms of the understanding of those previous circumstances that surround workplace bullying become of great importance in order to develop more effective lines of prevention and intervention (Saam, 2010; Einarsen and Hauge, 2006). The rates of bullying in the context of educational institutions seem relatively high when compared to those noted in the general population, which range from 2% to 14%. Our study denotes a prevalence workplace-bullying rate of 4.4% among teachers, a very different result from other studies. Likewise, Lewis (1999) finds that 18% of the lectures feels psychologically bullied at work, while Spratian (1995) concludes that 23% of the teachers at an American University admitted having feel bullied at work during the last ten months. Similarly, Björqvist et al. (1994) observe that 11% of University teachers feel bullied, a percentage that escalates up to 16% among those who combine teaching and researching duties. Jennifer, Cowie and Ananiadou (2003) place the rate of bullying among non-University teachers at 21.1%, while Herranz-Bellido et al. (2006) set it at 22.6% of University teachers. More recently, a study conducted at an American University by Keashly and Neuman (2008) found that as much as 32% of the respondents auto-identified themselves as bullying targets.

According to these results, it is estimated that workplace bullying rate for education employees arises larger than the predicted average when comparing the same parameter for the employees laboring in any other occupational activity or sector. In this sense, Zapf et al. (2003) provide a wide-ranging summary of European studies concluding that for public sector – service, health, education, and assistance– the prevalence of bullying arises higher than for private. A similar conclusion is reached by Hoel and Cooper (2000) in the United Kingdom who illustrate a more significant bullying incidence within public services, such as education or correctional assistances, and a lower prevalence in retail market and industrial sector.

Similarly, Soares' (2002) research shows that 4.4% of respondents out of a sample that included public education and health care employees, have been occasionally bullied by their patients or students in the exercise of their functions.

Academic literature is witnessing a prolific production of studies concerning bullying on specific types of occupations. On this subject, certain studies suggest that nursing staff members have been bullied 44.0% at some point of their working lives (Dellasega, 2009). Other occupations with bullying evidences include restaurant employees (Mathisen et al., 2008), teachers (Smith et al., 2003), university professionals (Mayhew et al., 2004; Bjorkqvist et al., 1994), healthcare workers (Ariza et al., 2013), business professionals (Salin, 2001), transportation workers (Mayhew et al., 2004), police officers (Waddington and Braddock, 1991) and managers (Ariza et al., 2014). Diverse explorations reflect multiple occupations just in the same study: blue collar workers, clerks and service workers, associate professionals, managers and professionals, etc. (Ortega et al., 2009; Niedhammer et al., 2007).

But which are really the causes that drive workplace bullying development within a concrete working cluster? Conceptualizing any organization as a whole entity results essential to conceive the phenomenon of bullying; it seems quite complicated to imagine one labor context as excessively independent or non-influential to trigger workplace bullying. Therefore, although early studies focused mainly on psychological characteristics of bullies and their victims, since the decade of the nineties several scholars have weighed more strongly the influence of some labor and structural characteristics of the organization on the individuals. In this line, the meta-analysis of Bowling and Beehr (2006) has pointed out certain organizational variables, as workplace bullying antecedents, worth to highlight: conflict and role ambiguity (Bowling and Beehr, 2006), work overload, stress, lack of autonomy, and absence of organizational fairness (Topa et al., 2007). Zapf et al.'s research (1996) evidences that monotonous and repetitive tasks happen to be more common among bullying victims.

Building upon the prior literature, this chapter develops a research model that links Job Demands, Job Resources, Work Stress, Motivation and Workplace Bullying. The most known and cited model of Job Demands-Resources (JD-R) in this research field is the one proposed by Demerouti and Bakker (2011), in which they theorize that the demands inherent to each job characteristics and the resources available for the employees are the drivers of two processes initially independent: ones that result in a general deterioration of health and others comprising a motivational incentive for the employee. Our model extends this idea by focusing on the effect of job resources on work stress and job demands on motivation. Additionally, as a core purpose of our study, we aim to assess the impact of both processes on the employees' overall welfare and their bullying perception.

After testing our hypotheses, the results reveal that teaching activity is under several tension focuses, which are rooted accentuated demands that teachers must face nowadays. These demands result in direct impacts on the employees' health, concretely on the stress level developed during their work (Hypothesis H1). Following our results, the main stressors within the academic environment are having to deal daily with angry customers that neither value nor respect the teacher's effort, the work overload, the performance of tasks that come into conflict with personal values, the high emotional demand of work, the accomplishment of monotonous tasks and having to take work to home during weekends. All of this generates feelings of anguish and frustration that, sooner or later, can lead to work-related stress. This conclusion is in line with the studies that adopt Organizational Health models as their core focus. These studies identified the defining characteristics of unhealthy schools: aggressions from the

pressure groups surrounding the school, incompetent school administrators, communication gaps between teachers, conflict, and low academic expectations (Hoy and Feldman, 1987). At the same time, our second hypothesis (H2) posited that the high vocational component of the teaching profession, coupled with the availability of certain resources that are unique and idiosyncratic of the teaching activity, generates among these a motivational process that can counterbalance the demands tied to it. In this way, our analysis indicates that job resources (such as perceiving a good salary, receiving feedback from the supervisor about the performance reached, the possibility of choosing the coworkers, career opportunities and the support from colleagues) have an important influence on motivation. As Nahrgang et al. (2011) indicate, job resources motivate employees towards engagement and mitigate burnout. By creating a supportive environment, organizations are not just achieving a safe workplace but are potentially increasing the motivation and health of their employees.

We could not find support for the impact of JR on work-related stress (Hypothesis 3), neither the effect of JD on the employees' motivation (Hypothesis 4). Therefore our results fail to provide evidence to support the view of Hakanen et al. (2006) who posited that certain resources such as support and recognition from superiors, innovation, and organizational climate may help teachers to face the exigent demands inherent to their jobs, to the extent that may soften the negative relationship between pupils' bad behavior and teachers' involvement.

On the other hand, we found support for the main focus of this research: the teachers' workplace-bullying perception. In this vein, as posited in hypotheses H5 and H6, When teachers are more stressed they are more likely to perceive a feeling of harassment, while among the more motivated ones this feeling gets reduced. From this perspective, bullying among teachers would result from an unstable set of balances between the stress experienced by these as a result of the demands that must be faced and the degree of intrinsic motivation that they raise due to the resources provided by the institution. The result of this dilemma is not random, but depends largely on the management carried out by academic authorities. School administrators are expected to act fairly and to be balanced towards teachers the creation of healthy school environments (Cemaloğlu, 2007). With regard to the purpose of this study, academic managers could incline the balance towards the side of the motivational processes, introducing changes in the design of jobs. For instance, they could reduce the working hours or avoid the most monotonous and complex tasks, by the demands side, either they could improve certain resources such as salary, feedback or interpersonal relationships among peers. The quality of interpersonal relations in educational organizations is such a critical issue that some authors assume that teachers' job satisfaction and their performance depend of it (Cemaloğlu, 2007). Performance evaluation systems could be also introduced in order to provide a clear and systematic feedback that helps to identify areas of improvement, or designing training policies and plans that allow employees acquire new technical skills and knowledge, thus expanding the catalogue of resources at its disposal to achieve a better performance of the functions and tasks in the workplace.

This research suggests that only those work environments in the education sector where resources have more weight than the demands can generate a healthy organizational environment conducive to reduce the negative effects of workplace bullying. For instance, Dollard and Bakker, (2010) found that psychological safety climate (PSC) was related to change in both job demands and resources overtime, and that work conditions respectively mediated the relationship between PSC and psychological health problems and work engagement. This way, it contributes to enhance the employees' welfare, which may in turn

improve service quality, efficacy, efficiency, and hence, organizational performance and productivity within a strategic and crucial sector for a nation's development such as education sector.

CONCLUSION

Workplace hostility stems as a serious and growing problem affecting a significant proportion of teachers. A victim of workplace bullying suffers in ways that may ultimately have serious consequences, such as depression; anxiety, fear or even panic when going to work; stress and, in some grave cases, could even lead to suicidal thoughts or acts (Campos et al., 2012). As a result of the severe negative consequences of workplace bullying on mental health and well-being of employees, and, hence, on the performance of the organization, it has evolved into a vital importance to understand the factors that contribute to its emergence and development (Bond et al., 2010). In this regard, the present study may contribute, with substantial implications, to the procurement of preventive measures against bullying in education.

The research model obtained in the present chapter is focused on the prediction of the dependent variable, in this case the workplace bullying among teachers. These findings sustain the much cited work environment hypothesis, which links bullying to a stressful work environment (e.g., Notelaers et al., 2010). Taking into account the Job Demands-Resources model, workplace bullying is pondered as a complex phenomenon that arises due to the dynamic interaction of work stress and motivation. Its findings enclose valuable implications to those organizations thriving and enhancing organizational performance. This work provides reasonable evidences that may be of significant applications for the responsible of human resource policy implementation; these school administrators might reduce organizational levels of workplace bullying by adjusting certain working conditions to those teachers especially susceptible to be bullied.

ABSTRACT

In this chapter, family socialization and its influence on bullying in the school context is discussed, considering parenting styles as a possible protective factor for aggressive behavior among peers. Then, a study analyzing the influence of parenting on bullying in a sample of Spanish adolescents is discussed. Recent research has confirmed that, in Spain, adolescents raised by indulgent parents have a similar adjustment to that of adolescents raised by authoritative parents. This study confirms the role of indulgent and authoritative parenting, both characterized by acceptance/involvement, as protective factors for bullying. Furthermore, both styles of socialization –indulgent and authoritative– also act as prevention factors for other behaviors related to bullying that denote school maladjustment, such as antisocial behavior, disruptive or undisciplined behavior, academic indifference, perception of violence from teachers, and academic, family and social self-esteem.

FAMILY SOCIALIZATION STYLES AS PROTECTIVE OR RISK FACTORS FOR BULLYING

In recent decades, school violence has greatly increased its social impact due to its negative consequences for the agents involved in the aggressive situation, especially important physical

* Corresponding Author's Email: m.castillo.fuentes@uv.es.

and psychological consequences in both aggressors and victims and negative consequences for the educational system and for society.

Bullying or aggressive behavior among peers is one of the most important school violence problems. An extensive body of research has analyzed different personal, social and contextual factors related to the involvement in these maladjusted behaviors, in order to develop effective prevention and intervention programs aimed at avoiding or reducing the high incidence of this problem. For example, with regard to personal factors, on the one hand, demographic variables like sex and age or academic year have been identified by the empirical research, and several studies coincide in pointing out that adolescent boys are more likely to get involved in these aggressive behaviors (Carlyle and Steinman, 2007; Liang, Flisher, and Lombard, 2007; Wang, Iannotti, and Luk, 2012). On the other hand, different studies have concluded that other personal risk factors are high impulsiveness and, consequently, difficulty with self-control, low frustration tolerance, poor social and coping skills, low self-concept and some emotional disorders such as depression and anxiety (Carlyle and Steinman, 2007; Shetgiri, Lin, Avila, and Flores, 2012; Wang, Nansel, and Iannotti, 2011).

Other risk factors considered in the scientific research are those related to the social context where children are raised. For example, living in conflictive and violent neighborhoods, which could be characterized, among other things, by the presence of violent gangs and drug dealing, increases the likelihood of developing aggressive behaviors (Gracia, Fuentes, García, and Lila, 2012; Jansen et al., 2012; Shetgiri et al., 2012).

School factors, such as the school resources available, school climate and cohesion, problem-solving strategies, teacher competence and the relationships among teachers and between teachers and students, are also considered to be important factors (Debnam, Johnson, and Bradshaw, 2014; Eliot, Cornella, Gregorya, and Fan, 2010; Waasdorp, Pasc, O'Brennand, and Bradshaw, 2011).

Despite the relevance of all these factors, empirical research highlights the need to consider the family context as the first social context in children's development and the main socialization agent that will influence children's adjustment in the different developmental contexts and in society (Berns, 2011; Espino, 2013; Gavazzi, 2011, 2013). Thus, different variables like the socioeconomic status, family structure and cohesion, perceived quality of parent-child relationships, parental drug use or the presence of conflicts at home, both between the parents and between parents and children, have been widely studied in relation to the development of children's aggressive behavior. For example, low socioeconomic status, low family cohesion, living in a broken home, and the presence of parental violent behavior at home have been identified as risk factors (Espelage, Low, Rao, Hong, and Little, 2013; Jansen et al., 2012), while living with both biological parents, family cohesion, perceiving a good relationship between the parents and between parents and children, and parental support and involvement have been identified as protective factors for children's violent behavior (Melander, Hartshorn, and Whitbeck, 2013; Spriggs, Iannotti, Nansel, and Haynie, 2007; García and Gracia, 2009, 2010; Gracia et al., 2012).

Another important family variable in the empirical research is parental socialization and its relationship with the development of adjusted and maladjusted behaviors in children. In this sense, most studies emphasize that the values, beliefs and attitudes toward school and education that parents transmit to their children in the socialization process will significantly influence their school adjustment (Fuentes, Alarcón, Gracia, and García, 2015; Pears, Kim, Capaldi, Kerr, and Fisher, 2013; Steinberg, Lamborn, Dornbusch, and Darling, 1992a). Traditionally, the

study of parental socialization and its influence on children's adjustment has been based on the classic theoretical model consisting of two orthogonal dimensions (acceptance/involvement and strictness/imposition) and four typologies (Darling and Steinberg, 1993; Maccoby and Martin, 1983); each of them represents a particular pattern of parental behavior in their children's socialization: authoritative style (high acceptance/ involvement and high strictness/imposition), indulgent style (high acceptance/involvement and low strictness/imposition), authoritarian style (low acceptance/involvement and high strictness/imposition), and neglectful style (low acceptance/involvement and low strictness/ imposition) (Lamborn, Mounts, Steinberg, and Dornbusch, 1991; Steinberg, Lamborn, Darling, Mounts, and Dornbusch, 1994; Maccoby and Martin, 1983).

Despite the agreement in the scientific literature about the importance of considering parental socialization as a significant factor that affects children's adequate psychosocial adjustment, there are important inconsistencies regarding the parenting style that would act as a protective or risk factor for the development of maladjusted behaviors like children's aggressive behavior, mainly when considering the cultural and social background where this relationship develops (García and Gracia, 2014; White and Schnurr, 2012).

Thus, in studies carried out fundamentally in Anglo-Saxon cultures, the authoritative style, characterized by high acceptance/involvement and high strictness/imposition, is considered a protective factor, followed by the authoritarian style, characterized by low acceptance/involvement and high strictness/imposition. By contrast, the neglectful style, which is characterized by the lack of both parental affection and parental imposition (low acceptance/involvement and low strictness/imposition), and even the indulgent parenting style, characterized by high acceptance/involvement and low strictness/imposition, have been identified as risk factors (Baumrind, 1991, 2012; Lamborn et al., 1991; Steinberg et al., 1992a, 1994). Similar results have been obtained for psychosocial adjustment. Children from authoritative families showed better psychological adjustment (e.g., higher self-esteem, higher resilience, and better use of adaptive strategies), higher school achievement (e.g., better academic competence, higher grade point average) and lower probabilities of having behavior problems (e.g., lower drug use and delinquency), while children from neglectful families obtained the worst results, and children from authoritarian and indulgent families showed mixed results (Aunola, Stattin, and Nurmi, 2000; Bahr and Hoffman, 2010; Garg, Levin, Urajnik, and Kauppi, 2005; Im-Bolter, Zadeh, and Ling, 2013; Kritzas and Gliber, 2005; Montgomery, Fisk, and Craig, 2008).

Another set of studies conducted with ethnic minority groups from the US (Afro-American: Baumrind, 1972; Pittman and Chase-Lansdale, 2001; Asian-American: Steinberg, Dornbusch, and Brown, 1992b; Chinese-American: Chao, 1994, 2001), with Asian and Middle Eastern societies (Dwairy, 2008; Dwairy and Achoui, 2006; Dwairy and Menshar, 2006), and with families with low socioeconomic status (Hoff, Laursen, and Tardif, 2002) identified the authoritarian style as a protective factor and an adequate parenting style for optimal psychosocial adjustment. Children from authoritarian families showed, for example, adequate mental health and the best academic achievement.

Finally, in a broad group of studies carried out in different Southern European and Latin-American countries, even in some cultural backgrounds where previous studies have broadly concluded that another parenting style is more appropriate (Iran: Kazemi, Ardabili, and Solokian, 2010; Sweden and UK: Calafat, García, Juan, Becoña, and Fernández-Hermida, 2014), the indulgent style, characterized fundamentally by parental affection but not by parental

imposition (high acceptance/involvement and low strictness/imposition), has been identified as a protective factor for children's aggressive behavior, followed by the authoritative style (high acceptance/involvement and high strictness/imposition). By contrast, the authoritarian (low acceptance/Involvement and high strictness/ imposition) and neglectful (low acceptance/involvement and low strictness/imposition) styles are considered risk factors. With regard to psychosocial adjustment, children from indulgent families showed better psychological adjustment (e.g., higher self-concept, lower emotional instability, and lower emotional unresponsiveness), higher school achievement (e.g., higher grade point average, and better use of self-regulated learning strategies) and lower probability of having behavior problems (e.g., lower drug use and delinquency), or at least the same results, as children from authoritative families, while children from authoritarian and neglectful families showed the worst psychosocial adjustment (Brazil: Martínez, Camino, Camino, and Cruise, 2014; Martínez and García, 2008; Martínez, García, and Yubero, 2007; Germany: Wolfradt, Hempel, and Miles, 2003; Italy: DiMaggio and Zappulla, 2014; Portugal: Rodrigues, Veiga, Fuentes, and García, 2013; Turkey: Erden and Uredi, 2008; Turkel and Tezer, 2008).

These findings are consistent with results obtained in Spain. The indulgent style is identified as a protective factor for children's aggressive behavior and as the parenting style related to the best results (or at least the same results as the authoritative style) in children's psychosocial adjustment (better psychological adjustment, better school adjustment and lower behavior problems), whereas the authoritarian and neglectful styles are identified as risk factors for the development of aggressive behavior and also as the parenting styles related to the worst psychosocial adjustment (Alonso-Geta, 2012; Cerezo, Casanova, de la Torre, and Carpio, 2011; Fuentes, Alarcón, García, and Gracia, in press; Fuentes, García, Gracia, and Alarcón, 2015; Garaigordobil and Aliri, 2012; Gracia et al., 2012; Martínez, Fuentes, García, and Madrid, 2013).

Considering this cross-cultural variation in the parenting style related to children's best psychosocial adjustment, there is not enough empirical evidence about the relationship between the parenting style and bullying or aggressive behavior among peers at schools in the Spanish cultural context. Therefore, the main objective of this chapter is to analyze which parenting style would act as a protective factor and which as a risk factor for the development of this maladjusted behavior among Spanish children. According to the results obtained in previous research conducted in Spain and related cultural contexts, it was expected that the indulgent style would be identified (alone or along with the authoritative style) as a protective factor, while the authoritarian and neglectful styles would be identified as risk factors.

STUDYING THE INFLUENCE OF PARENTING STYLES ON BULLYING

To analyze the influence of parenting on bullying among adolescents, we used a sample of 1114 Spanish adolescents (49.9% females and 50.1% males) from middle-class backgrounds in a large metropolitan area in Spain with over one million inhabitants. In addition to bullying, other related variables, some of them denoting school maladjustment, were also considered as outcome variables. These variables were: antisocial behavior, disruptive or undisciplined behavior, academic indifference, perception of violence from teachers, academic self-esteem, family self-esteem and social self-esteem.

Parenting styles were assessed using the *ESPA29 Parental Socialization Scale* (Musitu and García, 2001). On this scale, adolescents report the frequency of several parental practices (father's and mother's practices were asked about separately) in different situations with significant impact on the parent-child relationship in Western culture, using a contextual (Darling and Steinberg, 1993) and situational (Smetana, 1995) perspective. The adolescents were asked a total of 212 questions, 106 for each parent. Twenty-nine situations were sampled, 13 teenage compliance situations (e.g., "If somebody comes over to visit and I behave nicely") and 16 teenage noncompliance situations (e.g., "If I break or ruin something at home") to assess parental practices on a 4-point scale (1 = never, 4 = always). In each of the 13 compliance situations, the offspring had to rate the parenting practices of affection ("he/ she shows warmth") and indifference ("he/she seems indifferent"). In each of the 16 noncompliance situations, the offspring had to rate the parenting practices of dialogue ("he/ she talks to me"), detachment ("it's the same to him/her"), verbal scolding ("he/she scolds me"), physical punishment ("he/she spans me"), and revoking privileges ("he/she takes something away from me"). The family score for the acceptance/involvement dimension was obtained by averaging the responses on affection, dialogue, indifference, and detachment practices of both the father and the mother (in the latter two practices, the scores were inverted because they are inversely related to the dimension). The family score for the strictness/imposition dimension was obtained by averaging the responses on practices of verbal scolding, physical punishment and revoking privileges, performed by both the father and the mother. Hence, two dimensions measured family parenting styles (see Lamborn et al., 1991; Steinberg et al., 1994), so that higher scores represent a greater sense of acceptance/involvement and strictness/imposition (highest score on the two scales = 4). The factorial structure of the instrument has been confirmed in different studies (Martínez, García, Camino and Camino, 2011; Martínez, García, Musitu, and Yubero, 2012; Martínez, Musitu, García, and Camino, 2003).

The four parenting styles –authoritative, indulgent, authoritarian, and neglectful– were defined, after controlling for differences in sex and age, by dichotomizing the family scores on the acceptance/involvement and strictness/imposition dimensions using the median split (50th percentile). Thus, authoritative families were those who scored above the median on both dimensions, indulgent families scored above the median on acceptance/involvement and below it on strictness/imposition, authoritarian families scored below the median on acceptance/involvement and above it on strictness/imposition, and neglectful families scored below the median on both dimensions (Lamborn et al., 1991; Steinberg et al., 1994).

Bullying was assessed with the *Questionnaire on School Maladjustment Problems, QSMP* (Peralta, Sánchez, de la Fuente, and Trianes, 2007). This questionnaire was also used to evaluate other variables related to bullying and denoting school maladjustment, such as antisocial behavior, disruptive or undisciplined behavior, academic indifference and perception of violence from teachers. The QSMP has two versions, one for students and one for teachers. In this study, the students' version was used. The original version of the QSMP includes 66 items, scored on a scale from 1 (never) to 4 (always).

Finally, the academic, social and family dimensions of self-esteem in adolescents were evaluated with the *Multidimensional Self-Esteem Scale AF5* (García and Musitu, 1999). In this instrument, self-esteem is understood as multidimensional, hierarchically-ordered, and increasingly differentiated with age, based on Shavelson and colleagues' theoretical model (Byrne and Shavelson, 1996; Shavelson, Hubner, and Stanton, 1976). This 30-item scale assesses self-esteem in five domains: academic (e.g., "I do my homework well"), social (e.g.,

"I make friends easily"), emotional (e.g., reverse scored, "Many things make me nervous"), family (e.g., "I feel that my parents love me"), and physical (e.g., "I take good care of my physical health"). Each domain is measured with 6 items (99-point scale). Its factorial structure has been confirmed with both exploratory (García and Musitu, 1999, Martínez, 2003) and confirmatory (Fuentes, García, Gracia, and Lila, 2011a, 2011b; García, Gracia, and Zeleznova, 2013; García, Musitu, and Veiga, 2006; García, Musitu, Riquelme, and Riquelme, 2011; Murgui, García, García, and García, 2012) factor analyses, and no method effect appears to be associated with negatively worded items (Tomás and Oliver, 2004).

RESULTS OF THE STUDY

The analysis of variance of the relationship between parenting styles and bullying or aggressive behavior among peers shows that adolescents with indulgent and authoritative parents tend to participate less in these behaviors than adolescents from authoritarian and neglectful homes. The same results were found for the other behaviors analyzed reflecting school maladjustment problems (antisocial behavior, disruptive or undisciplined behavior, academic indifference and perception of violence from teachers). No differences were found between adolescents from indulgent and authoritative homes on any of these behaviors (see Figure 1), showing that both styles of socialization –indulgent and authoritative– can act as prevention factors for bullying and the other related behaviors analyzed. With regard to self-esteem, adolescents raised in indulgent and authoritative homes show higher academic, social and family self-esteem than adolescents raised in authoritarian and neglectful homes (see Figure 2). In line with other results analyzing the relationship between parenting and self-esteem in Spanish adolescents, indulgent parenting has similar or better results than authoritative parenting when children's self-esteem is considered (e.g., Fuentes et al., 2015; Martínez and García, 2007).

CONCLUSION

The results from previous research studying the different personal, social and contextual prevention and risk factors for the development of school violence, especially bullying or aggressive behaviors among peers, are presented in this chapter. Among these factors, the family context as children's first developmental context and main socialization agent is highlighted.

In this sense, empirical research has repeatedly shown the important influence of the different parental behaviors in the socialization process on the optimal psychosocial adjustment of children (Baumrind, 2012; Becoña et al., 2012; García and Gracia, 2014; Lamborn et al., 1991; Steinberg et al., 1994). Different studies have concluded that the values, beliefs and attitudes toward school and education that parents transmit to their children will significantly influence their school adjustment (Fuentes, Alarcón, Gracia et al., 2015; Pears et al., 2013; Steinberg et al., 1992a).

Thus, the main aim of this chapter was to analyze the relationships between parental socialization styles (authoritative, indulgent, authoritarian and neglectful) and aggressive behavior among peers at school, as well as other related variables (antisocial behavior, disruptive behavior, academic indifference, perception of violence from teachers, and the academic, family and social dimensions of self-esteem), in order to examine which parenting style would act as a protective factor and which would act as a risk factor in the Spanish context.

According to the results obtained in previous empirical research on children's psychosocial adjustment, it was expected that the indulgent style, characterized fundamentally by parental affection but not by parental imposition (high acceptance/involvement and low strictness/imposition), would be identified (alone or along with the authoritative style, characterized by high acceptance/involvement and high strictness/imposition) as a protective factor. By contrast, it was expected that the authoritarian style (low acceptance/involvement and high strictness/imposition) and the neglectful style (low acceptance/involvement and low strictness/imposition) would be identified as risk factors.

The results obtained were in line with those expected. Both the indulgent and authoritative styles were identified as protective factors for bullying because children from indulgent and authoritative families showed the least likelihood of getting involved in aggressive behaviors among peers. The authoritarian and neglectful styles were identified as risk factors because children raised in these homes showed the greatest likelihood of behaving aggressively toward their peers at school. Similar results were obtained for the other variables analyzed. On the one hand, children from indulgent and authoritative families obtained the lowest scores on the other school maladjustment criteria and the highest scores in the academic, social and family dimensions of self-esteem. On the other hand, children from authoritarian and neglectful families scored higher on the different school maladjustment criteria and lower on the self-esteem dimensions assessed.

These findings are consistent with previous research conducted in the Spanish cultural context (Alonso-Geta, 2012; Cerezo et al., 2011; Garaigordobil and Aliri, 2012; Fuentes, Alarcón, García et al., in press; Fuentes et al., 2015; García and Gracia, 2009, 2010; Martínez et al., 2013), and in related cultural contexts (DiMaggio and Zapulla, 2014; Martínez et al., 2014; Martínez et al., 2007; Martínez and García, 2008; Rodrigues et al., 2013). These studies have concluded that the indulgent parenting style is associated with the best psychosocial adjustment in adolescents, or that it offers at least the same results in children's adjustment as the authoritative style.

Both parenting styles, indulgent and authoritative, are characterized by high parental affection in the socialization process (high acceptance/involvement). However, only the authoritative style is also characterized by high parental imposition (high strictness/imposition).

Children from indulgent families obtained at least the same scores on all the adjustment and maladjustment criteria assessed as the children whose parents were characterized by the authoritative parenting style.

This result suggests that the high use of parenting practices pertaining to the acceptance/involvement dimension, such as parental warmth and affection, parental support and involvement in children's socialization, and the use of dialogue and reasoning with children, are essential for the optimal psychological and social adjustment of Spanish children.

However, a high use of parenting practices pertaining to the strictness/imposition dimension, such as parental control, supervision or firm discipline, is unnecessary or even harmful, unless these practices are accompanied by parental affection. In fact, the authoritarian style was identified as a risk factor for the development of bullying, and as the parenting style related to the worst results in the other criteria analyzed.

Therefore, it is important to consider the family context in the different prevention and intervention programs aimed at avoiding or reducing school violence problems, especially bullying, work on the educational strategies of parents in the socialization process, and encourage the adequate use of parenting practices related to children's optimal psychological and social adjustment.

Chapter 110

**PEER-TO-PEER VIOLENCE AND BULLYING:
EXAMINING THE FEDERAL RESPONSE***

U.S. Commission on Civil Rights

LETTER OF TRANSMITTAL

The President
The President of the Senate
The Speaker of the House

On behalf of the United States Commission on Civil Rights I am pleased to transmit this report, *Peer-to-Peer Violence and Bullying, Examining the Federal Response*, pursuant to Public Law 103-419. The purpose of the report is to examine the role played by the U.S. Departments of Education and Justice in addressing peer-to-peer discrimination on the basis of race, national origin, religion, disability, sex and/or LGBT status.

To that end, the Commission gathered enforcement data from the Departments of Education and Justice and convened a day-long briefing on the subject of peer-to-peer violence and bullying. Twenty presenters participated in the briefing. Among the panelists invited to the briefing were: current and former federal government officials, academics, and representatives from a diverse set of advocacy organizations. In addition, the Commission received numerous written submissions from the public, academics, and advocacy organizations.

Based on the evidence gathered by the Commission, we conclude that despite the harm that peer-to-peer bullying and harassment due to a student's membership in certain classes, such as race, religion, or sexual orientation, current federal laws (and the laws of many states) do not fully protect all students from peer-to-peer bullying and harassment resulting from animus toward their group status.

Specifically, the Commission's findings, by majority vote, are:

* This is an edited, reformatted and augmented version of a report issued September 2011.

- 1) Bullying and harassment, including bullying and harassment based on sex, race, national origin, disability, sexual orientation, or religion, are harmful to American youth.
- 2) Current federal civil rights laws do not provide the U.S. Department of Education with jurisdiction to protect students from peer-to-peer harassment that is solely on the basis of religion.
- 3) The current federal civil rights laws do not protect students from peer-to-peer harassment that is solely on the basis of sexual orientation.

To better record the incidence of harassment based solely on sexual orientation or solely on religion, we recommend that the Departments adopt more detailed tracking methods regarding the complaints they receive. To better assist state and local officials to comply with their responsibilities under federal law, we recommend that the Department of Education strive to use consistent language and provide concrete examples in the guidance documents that it produces.

On August 12, 2011, the Commission approved this report. The vote was as follows: Commissioners Achtenberg, Castro, Thernstrom and Yaki supported the approval of the report; Commissioners Gaziano, Heriot and Kirsanow opposed the approval of the report; Commissioner Kladney abstained from voting on the report due to the fact that August 12th was his first Commission meeting.

For the Commissioners,
Martin R. Castro Chairman

SECTION 1. EXECUTIVE SUMMARY

This report focuses on the government's efforts to enforce federal civil rights laws with respect to peer-to-peer violence based on race, national origin, sex, disability, religion, and sexual orientation or gender identity.

The Commission examined the nature and incidence of peer-to-peer violence in public K-12 schools and studied the types of peer-to-peer violence faced by students, as well as the effects of such violence. The Commission further reviewed the policies and procedures employed by the United States Departments of Education and Justice in enforcing prohibitions against peer-to-peer violence.

The Commission, by majority vote, concluded that bullying and harassment, including bullying and harassment based on sex, race, national origin, disability, sexual orientation, or religion, are harmful to American youth, and developed findings and recommendations to address the problem, including the following recommendations:

- The U.S. Departments of Education and Justice should track their complaints/inquiries regarding sexual harassment or gender-based harassment by creating a category that explicitly encompasses LGBT youth.

- The U.S. Departments of Education and Justice should track complaints that they receive regarding harassment based solely on sexual orientation that are closed for lack of jurisdiction.
- The U.S. Department of Education should track complaints that it receives regarding harassment based solely on religion that are closed for lack of jurisdiction.
- The U.S. Department of Education should consider issuing a new Dear Colleague Letter regarding the First Amendment implications of anti-bullying policies. The new Letter should provide concrete examples to clarify the guidance that the Department of Education previously provided in its Dear Colleague Letter on the First Amendment dated July 28, 2003.

SECTION 2. INTRODUCTION AND BACKGROUND

Peer-to-Peer Violence in K-12 Public Schools

On March 11, 2011, the U.S. Commission on Civil Rights, by majority vote, selected peer-to-peer violence and bullying as the topic for its annual, statutorily mandated enforcement investigation.¹ The Commission elected to explore the federal enforcement of civil rights laws with respect to peer-to-peer violence based on race, national origin, sex, disability, religion, and sexual orientation or gender identity.²

On May 13, 2011, the Commission held a day-long briefing on peer-to-peer violence and bullying. Twenty panelists, including government officials, academics, attorneys, and advocates participated. Key elements of the briefing are included in this report.

This report examines the work of the United States Departments of Education (ED) and Justice (DOJ) in enforcing prohibitions against discrimination and harassment as they relate to bullying and other peer-to-peer violence in public K-12 schools. This Section provides information on the incidence of peer-to-peer violence as well as the unique problems associated with peer-to-peer violence as it relates to various demographic groups. It also provides background information on relevant legal protections, highlighting statutes enforced by ED and DOJ. Sections Three and Four set forth the processes employed by ED and DOJ, respectively, in monitoring and enforcing prohibitions against peer-to-peer violence and provide data regarding ED and DOJ's enforcement activities. Section Five is an overview of ED's October 2010 Dear Colleague Letter addressing the legal obligations of schools related to bullying and harassment. Section Six discusses jurisdictional issues related to ED and DOJ's use of existing laws to combat peer-to-peer violence where the victims are in part targeted based on their sexual orientation or gender identity, or based on their religion. Section Seven explores other concerns related to the current federal response to peer-to-peer violence, including critiques based on the enforcement standards used by ED, the appropriateness of a large-scale federal response versus the need for state and local control, and the First Amendment.

What Is Bullying?

Although the Commission declines to endorse a single and authoritative definition of "bullying," several entities have put forth definitions that are informative as to the nature and variance of the issue. For example, the National Center for Education Statistics and the Bureau of Justice Statistics have described bullying to include "being made fun of; being the subject of rumors; being threatened with harm; being pushed, shoved, tripped, or spit on; being pressured into doing things [one] did not want to do; excluded [sic] from activities on purpose; and having property destroyed on purpose."³ Similarly, the American Psychological Association describes bullying as follows:

Commonly labeled as peer victimization or peer harassment, school bullying is defined as repeated physical, verbal or psychological abuse of victims by perpetrators who intend to cause them harm. The critical features that distinguish bullying from simple conflict between peers are: intentions to cause harm, repeated incidences of harm, and an imbalance of power between perpetrator and victim. Hitting, kicking, shoving, name-calling, spreading of rumors, exclusion and intimidating gestures (e.g., eye rolling) by powerful peers are all examples of behaviors that constitute abuse that is physical, verbal or psychological in nature.⁴

In addition, the National Education Association has defined bullying as:

[I]ntentional and repeated acts of a threatening or demeaning nature that occur through direct verbal (e.g., threatening, name calling), direct physical (e.g., hitting, kicking), and indirect (e.g., spreading rumors, influencing relationships, cyberbullying) means that typically occur in situations in which there is a power or status difference.⁵

What Harassment Is Subject to Federal Jurisdiction?

Bullying triggers federal civil rights laws where it meets the heightened legal standard for "harassment." That is, it targets students based on a protected classification, it creates a hostile environment, and schools have notice of the conduct but fail to address it. As described by ED's Assistant Secretary for Civil Rights Russlynn Ali:

[S]chool districts violate the federal civil rights laws that OCR enforces when harassment based on race, color, national origin, sex, or disability is sufficiently serious to create a hostile environment, and school employees encourage, tolerate, do not adequately address, or ignore the harassment.⁶

Likewise, according to Jocelyn Samuels, Senior Counselor to DOJ's Assistant Attorney General for Civil Rights, "[DOJ]'s authority goes to harassment which is physical or verbal or other conduct that is sufficiently severe or pervasive to create a hostile environment that interferes with a student's ability to learn."⁷

Because federal case law establishes a high bar for school liability for incidents of student-on-student harassment,⁸ not all forms of bullying are subject to federal jurisdiction, and ED and DOJ do not get involved in typical schoolyard bullying and teasing. As Ms. Samuels explains, "We do not have jurisdiction and would not take action against single incidents of playground

taunting absent something like physical conduct that made a single incident sufficiently severe or pervasive to create a hostile environment."⁹

It is important to keep these distinctions in mind while reviewing this report. Federal civil rights laws—and the federal government's enforcement of those laws—are limited to heightened incidents of harassment that do not include typical schoolyard bullying unless that bullying creates a hostile environment. As such, incidents of bullying reported in surveys and statistical studies in this report do not necessarily meet the threshold for federal jurisdiction.

Peer-to-Peer Violence Generally¹⁰

Acts of bullying, violence, and harassment are widespread in K-12 schools. The School Survey on Crime and Safety (SSCS), sponsored by ED's National Center for Education Statistics (NCES), found that 25 percent of schools reported that bullying took place amongst their students on a daily or weekly basis.¹¹ Likewise, the School Crime Supplement to the National Crime Victimization Survey (SCS-NCVS), sponsored by DOJ's Bureau of Justice Statistics, found that about 32 percent of students aged 12 to 18 reported having been bullied in their schools during the 2007 school year.¹² Twenty-one percent of the bullied students said that they experienced bullying once or twice per month, 10 percent said they were bullied once or twice per week, and 7 percent responded that they were bullied on a nearly daily basis.¹³ Only 36.1 percent of the bullied students responded that they had notified an adult at school about the incident or incidents.¹⁴ Similarly, the Youth Risk Behavior Survey (YRBS), sponsored by the Centers for Disease Control and Prevention (CDC), found that 19.9 percent of high school students reported being bullied on school property during the prior 12 months.¹⁵

Studies conducted by the private sector have found an even higher prevalence of bullying. A recent study of 43,000 students by the Josephson Institute of Ethics found that 47.1 percent of American high school students reported having been bullied, teased, or taunted in the previous year in a way that seriously upset them.¹⁶ The study also found that 49.8 percent of high school students admitted to having bullied, teased, or taunted someone within the past year,¹⁷ and that 33.4 percent of high school students believed that physical violence, such as fighting, bullying, and intimidation, was a big problem at their school.¹⁸

A 2011 study by the National Education Association found that 87 percent of school staff reported witnessing bullying. Specifically, 25 percent of school staff reported witnessing bullying once per month, 21 percent reported witnessing bullying 2 to 3 times per month, 16 percent reported witnessing bullying once per week; 15 percent reported witnessing bullying several times per week; and 9 percent reported witnessing bullying on a daily basis.¹⁹ Of the staff surveyed, 43 percent perceived bullying to be a moderate or major problem.²⁰

Furthermore, in recent years, the advent and widespread use of new technologies such as the Internet²¹ and cellular phones²² has led to new methods of bullying, often called "cyberbullying." Cyberbullying has been defined to include incidents in which classmates post hurtful information about a student on the Internet or make unwanted contact through instant messaging or text messaging that threatens or insults the student.²³ The recent growth of popularity of social networking sites (such as Facebook and MySpace) and video-sharing websites (such as YouTube) has led to increased reports of cyberbullying.²⁴ Though estimates do vary, one study found that about 20 percent of students that are 11 to 18 years of age indicate they have been a victim of cyberbullying at some point in their life.²⁵

Cyberbullying can have several negative effects on victims; many students have reported feeling sad, depressed, angry, and frustrated because of cyberbullying, while many expressed they were afraid or embarrassed to attend school.²⁶ Indeed, there are three factors that can make cyberbullying even more devastating than traditional bullying: (1) because cyberbullies can be anonymous or use false names, victims do not always know who is targeting them or why,²⁷ (2) the viral nature of cyberbullying enables the bully to reach a large audience in a short amount of time or involve a large group of bullies in the behavior,²⁸ and (3) cyberbullying can be substantively more cruel because it typically takes place from a distant location where the bully does not see the immediate impact of his or her actions.²⁹

While all bullying is harmful to America's youth, some experts believe that bullying based on students' identities—such as their sex, race, ethnicity or national origin, disability, sexual orientation or gender identity, or religion—can be particularly damaging.³⁰ Unfortunately, these forms of bullying are all too common in American schools. The SCS-NCVS found that 9.7 percent of students ages 12 to 18 reported being targeted by "hate-related words" in the 2007 school year.³¹ Two percent of all students reported being targeted based on gender, 4.6 percent based on race, 2.9 percent based on ethnicity, 1.0 percent based on disability, 1.0 percent based on sexual orientation, and 1.6 percent based on religion.³²

A 2007-2009 survey of California students, called the California Healthy Kids Survey (CHKS) and funded by the California Department of Education, found higher rates of identity-based bullying. The study found that 27 percent of all students in grades 7, 9, and 11 reported being subjected to identity-related bullying or harassment.³³ Eleven percent reported harassment based on gender (male or female), 18 percent based on race, ethnicity, or national origin, 9 percent based on physical or mental disability, 12 percent based on actual or perceived sexual orientation, and 11 percent based on religion.³⁴ This report addresses each category of bullying in turn.

Sex

Bullying based on sex takes many forms. It includes sexual harassment, which is unwanted conduct of a sexual nature. Some examples can include sexual propositions, pressuring for sexual favors, touching of a sexual nature, sexual gestures, telling sexual or dirty jokes, or spreading sexual rumors.³⁵ Sex-based harassment likewise includes sexual violence such as rape, sexual assault, sexual battery, and sexual coercion.³⁶ And finally, sex-based bullying includes bullying, harassment, and violence that is not sexual in nature, but is instead due to the individual's sex and/or non-conformity to sex stereotypes.³⁷ Examples can include harassment of a girl for participating in a sport that is considered unfeminine;³⁸ bullying a girl for being pregnant;³⁹ or harassing a boy for his effeminate mannerisms.⁴⁰ Sex-based bullying, harassment, and violence can involve boys targeting girls, girls targeting boys, and members of the same sex targeting each other.⁴¹

While statistics on sex-based bullying in K-12 schools are somewhat limited, a 2001 study by the American Association of University Women (AAUW) found that 81 percent of students in grades 8 to 11 reported experiencing sexual harassment, including 83 percent of girls and 79 percent of boys.⁴² Twenty-seven percent of the students surveyed, including 30 percent of girls and 24 percent of boys, said that they were sexually harassed often.⁴³ Seventy-six percent of students reported that they experienced nonphysical harassment often, occasionally, or rarely,⁴⁴

while 58 percent reported experiencing physical harassment often, occasionally, or rarely.⁴⁵ And 44 percent of girls and 20 percent of boys reported that they were afraid of being sexually harassed at school.⁴⁶

In addition, in the School Survey on Crime and Safety (SSOCS), sponsored by the U.S. Department of Education's National Center for Education Statistics, schools reported 800 incidents of rape and 3800 incidents of sexual battery not involving rape in the 2007-2008 school year.⁴⁷ The AAUW study found that 12 percent of boys and 9 percent of girls in grades 8 to 11 reported that they had been forced to do something sexual other than kissing.⁴⁸

Such sexual harassment causes students' education to suffer. According to the AAUW study, 24 percent of students subjected to sexual harassment reported that the harassment made them less likely to talk in class; 20 percent reported that the harassment made it difficult for them to pay attention in class; 22 percent of the students reported that the harassment made them not want to go to school; and 16 percent reported that, as a result of the harassment, they actually stayed home from school or cut a class.⁴⁹ In addition, 11 percent of students subjected to sexual harassment reported that the harassment caused them to make a lower grade in a class than they thought they otherwise would have.⁵⁰

Sex-based bullying can harm both female and male students in other ways as well. According to the AAUW study, of the students—boys and girls—who reported being subjected to sexual harassment, 47 percent reported feeling very or somewhat upset about the incident.⁵¹ In addition, 32 percent reported that they felt self-conscious, 43 percent reported that they felt embarrassed, 23 percent reported that they felt afraid or scared, 24 percent reported feeling less sure of themselves and less confident, 17 percent reported feeling confused about who they are, and 19 percent reported doubting whether they can have a happy romantic relationship.⁵² These feelings were particularly salient amongst girls. Of the *girls* who reported being subjected to sexual harassment, 44 percent reported that they felt self-conscious, 53 percent reported that they felt embarrassed, 33 percent reported that they felt afraid or scared, 32 percent reported feeling less sure of themselves and less confident, 22 percent reported feeling confused about who they are, and 25 percent reported doubting whether they can have a happy romantic relationship.⁵³ Where the sexual harassment was physical, even more students reported these emotional responses. Of those students—boys and girls—subjected to *physical* harassment, 38 percent reported that they felt self-conscious, 48 percent reported that they felt embarrassed, 28 percent reported that they felt afraid or scared, 28 percent reported feeling less sure of themselves and less confident, 21 percent reported feeling confused about who they are, and 23 percent reported doubting whether they can have a happy romantic relationship.⁵⁴

Race/National Origin

The California Healthy Kids Survey conducted in 2007-2009 found that when youth in California were bullied or harassed on school property, the most common specific reason cited was because of their race or national origin, with about 18 percent of students in grades 7, 9, and 11 reporting at least one bullying incident in the past year for this reason.⁵⁵ The problem is not limited to one specific racial or ethnic group. When results from 9th and 11th grade students are broken down by race and ethnicity, African-American students reported being bullied or harassed due to their race or ethnicity at the highest rate—23 percent.⁵⁶ Twenty-two percent of Asian-American students, 22 percent of Native Hawaiian or Pacific Islander students, and 20

percent of Native American students reported being harassed due to their race, ethnicity, or national origin as well.⁵⁷

Examples of racial harassment include ethnic slurs and derogatory ethnic comments, ethnic jokes, and criticisms of behaviors or physical features typically attributed to a certain race or ethnicity. For instance, a form of intra-racial bullying occurs when an African-American student is accused by another African-American student of “acting white,” because the student exhibits certain behaviors,⁵⁸ such as showing enthusiasm for schoolwork, studying too much, or maintaining certain cultural patterns of behavior including dress, speech, and music choice.⁵⁹ A recent study of 166 gifted African-American students in Ohio found that 66 percent reported knowing someone who was ridiculed for doing well in school.⁶⁰

Although statistical research on race- and national-origin-based harassment has been somewhat limited, DOJ activity provides anecdotal evidence of the kinds of race-based harassment that has occurred. For instance, in 2010, DOJ reached a settlement agreement with the Philadelphia, Pennsylvania School District, addressing harassment of Asian-American students at South Philadelphia High School that, in December 2009, led to a day-long attack by roving groups of students against the school’s Asian-American student population; by the end of the day, more than two dozen Asian-American students were attacked, and 13 of them were sent to the emergency room.⁶¹ And in April 2011, DOJ reached a settlement agreement with a school district in Owatonna, Minnesota, resolving an investigation into the race- and national-origin harassment of Somali Americans that led to a fight among 11 white and Somali-American students.⁶²

Disability

Incidents of bullying, harassment, and teasing of students with disabilities are also widespread.⁶³ Because bullies tend to target peers who appear vulnerable, students with disabilities are especially susceptible to physical or verbal attacks.⁶⁴ Indeed, research has shown that children with disabilities are bullied more often than children without disabilities. Though research regarding the connection between bullying and disability is fairly limited (a review of United States research in 2009 stated that only 10 studies had been conducted in the United States on the subject), such research seems to indicate that students with disabilities are two to three times more likely than students without disabilities to be victims of bullying.⁶⁵

In a 2009 study of parents of children with Asperger Syndrome, 94 percent reported that their children had been bullied.⁶⁶ Additionally, 65 percent reported that their children had been victimized by peers within the past year, while 50 percent reported that their children were scared by their peers.⁶⁷

Peer-to-peer bullying of students with disabilities tends to be persistent.⁶⁸ In one study, parents of children on the autism spectrum reported that nearly 39.6 percent of their children had been bullied for more than a year, with another 20.4 percent reporting that bullying took place over several months.⁶⁹

Disability harassment and bullying are of special concern because students with disabilities could have a difficult time responding to bullying behavior if they have difficulty understanding social cues and norms.⁷⁰ Further, because some students with disabilities have difficulty communicating, their victimization by bullies sometimes goes unreported.⁷¹

Lesbian, Gay, Bisexual, and Transgender (LGBT)⁷²

At least one study has found that, after physical appearance, many students report that actual or perceived sexual orientation is the most common reason for bullying, name-calling, or harassment in schools.⁷³ Many believe that anti-LGBT bullying results from general animus toward LGBT students and a stigmatization of homosexuality.⁷⁴

Surveys report that anti-LGBT bullying is rampant in American schools. According to a 2009 survey by the Gay, Lesbian and Straight Education Network (GLSEN 2009 Survey), 84.6 percent of LGBT youth were verbally harassed, 40.1 percent were physically harassed, 18.8 percent were physically assaulted at school in the previous year because of their sexual orientation,⁷⁵ and 52.9 percent of LGBT students suffered from cyberbullying.⁷⁶ The same survey found that 61.1 percent of LGBT students reported that they felt unsafe at school because of their sexual orientation;⁷⁷ similarly, a 2005 survey by GLSEN and Harris Interactive found that LGBT students were three times as likely as non-LGBT students to feel unsafe at school.⁷⁸

Surveys of students in California have found similarly high results. In a 2003 student survey by the California Safe Schools Coalition and the Gay-Straight Alliance Network, called the Preventing School Harassment (PSH) survey, 65 percent of LGBT students reported being harassed or bullied based on their actual or perceived sexual orientation.⁷⁹ The same report found that 91 percent of students surveyed reported having heard others make negative remarks based on sexual orientation.⁸⁰ The 2007-2009 California Healthy Kids Survey found that 12 percent of all 7th, 9th and 11th grade students in California's total student population reported being harassed or bullied because they were gay or lesbian, or because someone thought they were gay or lesbian.⁸¹ In the PSH study, 46 percent of students, asked whether their schools were safe for LGBT students, reported that this statement was "not at all true" or "a little true."⁸²

Similarly, Professor Mark Friedman, of the University of Pittsburgh Graduate School of Public Health, found that "sexual minority youth were 170 [percent] more likely [than heterosexual students] to be assaulted at school," and that 40 percent of lesbians, 44 percent of bisexual females, 43 percent of gay males and 50 percent of bisexual males had been assaulted at school.⁸³ This finding was based on a meta-analysis, comparing aggregate data from a number of independent studies.⁸⁴

Several studies have shown that LGBT students' academics suffer as a result of bullying based on sexual orientation. The GLSEN 2009 Survey found that LGBT students subjected to high levels of anti-LGBT bullying were about three times as likely to have been absent from school in the previous month.⁸⁵ It also found that LGBT students achieved lower grades when they were subjected to more frequent victimization,⁸⁶ and that a correlation exists between victimization and LGBT students' plans not to pursue post-secondary education.⁸⁷ A report by the California Safe Schools Coalition and the 4-H Center for Youth Development at the University of California, Davis likewise found that students in California who were harassed based on actual or perceived sexual orientation were more than three times as likely to have skipped at least one day of school in the previous month because they felt unsafe, and that 24 percent of students who were harassed based on actual or perceived sexual orientation reported usual grades of Cs or lower (compared to 17 percent of students who were not harassed).⁸⁸ Similarly, Professor Friedman's meta-analysis concluded that "sexual minority youth were ... 240 [percent] more likely [than heterosexual youth] to miss school due to fear that they would be unsafe at school or on [their] way to or from school," and that 16 percent of lesbian females,

23 percent of bisexual females, 14 percent of gay males, and 23 percent of bisexual males missed school for this reason.⁸⁹

Bullying based on sexual orientation can be extremely traumatic for students—perhaps even more so than bullying that is not based on a student's identity (*i.e.*, their sex, race, ethnicity, national origin, disability, sexual orientation, or religion).⁹⁰ Research shows that this is the case even though LGBT students do not have inherent vulnerabilities that would lead to such psychological stress.⁹¹ Numerous studies have found a mental-health impact resulting from anti-LGBT harassment.⁹² According to the California Safe Schools Coalition report, students in California that were harassed based on actual or perceived sexual orientation were more likely to report smoking, drinking alcohol, and drug use,⁹³ and were nearly four times more likely than non-harassed students to have carried a weapon to school in the previous year.⁹⁴ In addition, the GLSEN 2009 Survey found that LGBT students subjected to bullying were more likely to suffer from depression, anxiety, and low self-esteem.⁹⁵ Tragically, numerous studies have also found that LGBT students are more likely to consider⁹⁶ or attempt⁹⁷ suicide⁹⁸—a statistic that is borne out by anecdotal evidence as well.⁹⁹ The psychological effects of anti-LGBT bullying have been found to last long after adolescence.¹⁰⁰

Religion

Bullying based on students' religion is also a problem in America's schools. Recent media reports give demonstrative, albeit largely anecdotal, evidence of the issue.

Bullying of Muslim students has reportedly increased since the September 11, 2001 terrorist attacks.¹⁰¹ In one incident during the 2009-2010 school year, a middle school student in Staten Island, NY was taunted, teased, and ultimately attacked by his classmates because he was Muslim.¹⁰² The student told the *New York Post*, "They punched me. They spit in my face. They tripped me on the floor. They kicked me with their feet and punched me And as they were kicking and laughing, they kept saying, 'You f---ing terrorist, f---ing Muslim, you f-- -ing terrorist.'"¹⁰³ Sikh children have also reported an increase of bullying incidents since September 11. Although the Sikh religion is distinct from Islam, students purportedly target Sikh students out of confusion stemming from Sikhs' visible religious articles such as turbans and uncut hair.¹⁰⁴ A 2010 survey by the Sikh Coalition, conducted in the San Francisco Bay Area in California, found that 47 percent of local Sikh youth were subjected to bullying.¹⁰⁵ Of the boys who wear turbans (or patkas), 74 percent reported being subjected to bullying.¹⁰⁶ The survey found bullying to be most prevalent in Alameda County, where 86 percent of Sikh boys reported being targeted.¹⁰⁷ Likewise, a 2007 Sikh Coalition survey of Sikh youth in New York City found that 58.4 percent of local Sikh students had been subjected to bullying.¹⁰⁸ The survey found that 62.2 percent of boys who wear turbans (or patkas) reported that they were bullied and 42 percent reported being physically hit or involuntarily touched.¹⁰⁹ In the borough of Queens, as high as 77.5 percent of boys reported being bullied.¹¹⁰

Religion-based bullying is not limited to Muslims and Sikhs. Media reports in recent years describe students in numerous schools engaging in a so-called "Kick a Jew Day," where groups of students target and kick their Jewish classmates.¹¹¹ And the U.S. Department of Education's Office for Civil Rights has received complaints of students being harassed for their Christian faith.¹¹²

Legal Protections

This report addresses federal efforts to enforce prohibitions on peer-to-peer violence rooted in discrimination that takes place in public K-12 schools. Several civil rights statutes protect students from such harassment, including Title IX of the Education Amendments of 1972, Title VI of the Civil Rights Act of 1964, Section 504 of the Rehabilitation Act of 1973, and Title II of the Americans with Disabilities Act.¹¹³

These statutes apply to private suits for damages, ED's administrative enforcement, and both private and DOJ suits for injunctive relief. As a background to ED and DOJ's enforcement efforts, this section discusses the legal standards developed by courts in the context of private suits for damages. Both ED and DOJ use somewhat different legal standards in their administrative enforcement and suits for injunctive relief, respectively.¹¹⁴

Title IX

Title IX of the Education Amendments of 1972 (Title IX) prohibits public and private schools that receive federal financial assistance from discriminating on the basis of sex.¹¹⁵

Schools in violation of Title IX can be subject to termination of their federal funding or other administrative remedies,¹¹⁶ or to civil suit for damages or injunctive relief.¹¹⁷

Courts treat sexual harassment as a form of sex discrimination prohibited by Title IX, though the statute does not reference it directly. In *Franklin v. Gwinnett County Public Schools*, the Supreme Court held that teacher-on-student sexual harassment qualifies as sex-discrimination under Title IX.¹¹⁸ The Court expanded that holding in *Davis v. Monroe County Board of Education* to include student-on-student sexual harassment as well.¹¹⁹ In addition to sexual harassment, courts have also defined sex discrimination to include sexual violence¹²⁰ and sex-stereotyping.¹²¹

In private suits for damages, courts have set a high bar for school liability for peer-to-peer harassment under Title IX.¹²² First, the harassment at issue must be "so severe, pervasive, and objectively offensive that it can be said to deprive the victims of access to the educational opportunities or benefits provided by the school."¹²³ Second, school officials "with the authority to take corrective action to end the discrimination"¹²⁴ must have actual knowledge of the conduct.¹²⁵ And finally, those officials must have been "deliberately indifferent" to the sexual harassment.¹²⁶

Title VI

Title VI of the Civil Rights Act of 1964 (Title VI) prohibits public and private schools that receive federal financial assistance from discriminating on the basis of race, color, or national origin.¹²⁷ As with Title IX, schools in violation of Title VI can be subject to termination of their federal funding or other administrative remedies,¹²⁸ or to civil suit for damages or injunctive relief.¹²⁹ Because the language of Titles VI and IX is nearly identical, courts have generally applied the same standards to peer-to-peer harassment under Title VI that the Supreme Court developed regarding peer-to-peer harassment under Title IX.¹³⁰ As with Title IX, in private suits for damages the race-, color- or national-origin-based harassment must be "so severe, pervasive, and objectively offensive" that it deprives students of educational opportunities or benefits;¹³¹ school officials must have actual knowledge of the conduct;¹³² and the officials must be "deliberately indifferent" to the harassment.¹³³

Section 504 of the Rehabilitation Act of 1973 and Title II of the Americans with Disabilities Act

Courts have also found that both Section 504 of the Rehabilitation Act of 1973 (Section 504) and Title II of the Americans with Disabilities Act of 1990 (Title II) protect students from peer-to-peer harassment based on disability. Section 504 prohibits public and private schools that receive federal financial assistance from discriminating against students due to disability.¹³⁴ Likewise, Title II¹³⁵ prohibits public entities, including state or local governments, from discriminating against individuals due to disability.¹³⁶ Both statutes state that violators are subject to the same remedies as under Title VI,¹³⁷ which include loss of federal funding, or civil suit for damages or injunctive relief.¹³⁸ Because they are so similar, courts generally analyze Section 504 and Title II together when addressing claims related to peer-to-peer violence.¹³⁹

Furthermore, because the texts of Section 504 and Title II mirror the language used in Titles IX and VI, several courts have analyzed peer-to-peer harassment of students with disabilities under the framework set forth by the Supreme Court in *Davis*.¹⁴⁰ In order to make a claim in private suits for damages, students must allege that, due to their disability, they have suffered from harassment "so severe, pervasive, and objectively offensive"¹⁴¹ that it deprives them of educational opportunities or benefits; that school officials had actual knowledge of the conduct;¹⁴² and that the officials were "deliberately indifferent" to the harassment.¹⁴³

SECTION 3. FEDERAL ENFORCEMENT EFFORTS: THE DEPARTMENT OF EDUCATION

The Department of Education's Office for Civil Rights (OCR) plays the dominant role in evaluating complaints alleging discrimination based on race/national origin, sex, and disability in schools. From 2005 to March 21, 2011,¹⁴⁴ OCR received 4,433 complaints alleging harassment based on race/national origin, sex, and disability.¹⁴⁵

In addition to complaints processing, OCR is involved in a number of other activities related to combating bullying and other forms of peer-to-peer violence. In these efforts, ED has joined the Departments of Health and Human Services, Justice, Defense, Agriculture, and Interior, as well as the National Council on Disability and the Federal Trade Commission, as members of the Federal Partners in Bullying Prevention Steering Committee. In addition to holding a summit in August 2010, the Steering Committee participated in a White House-sponsored Conference on Bullying, and launched StopBullying.gov, a website that provides information on preventing bullying.¹⁴⁶ ED also works with the Departments of Labor, Health and Human Services, Housing and Urban Development, and the Office of National Drug Control Policy, as part of the National Forum on Youth Violence Prevention, which supports the creation of youth-violence prevention initiatives in six communities in the United States.¹⁴⁷

The Department of Education's Civil Rights Complaint Processing System

OCR enforces Title VI of the Civil Rights Act of 1964, Title IX of the Education Amendments of 1972, Section 504 of the Rehabilitation Act of 1973, the Age Discrimination

Act of 1975, Title II of the Americans with Disabilities Act of 1990, and the Boy Scouts of America Equal Access Act.

Titles VI and IX, Section 504, and the Age Discrimination Act grant OCR jurisdiction over institutions that receive federal financial assistance from ED, as well as other institutions for which other federal agencies have delegated authority to OCR.¹⁴⁸ Title II grants OCR jurisdiction over public elementary and secondary education systems and institutions, public institutions of higher education and vocational education (other than schools of medicine, dentistry, nursing, and other health-related schools), and public libraries, even if these institutions do not receive federal financial assistance.¹⁴⁹ The Boy Scouts Act grants OCR jurisdiction over public elementary schools, public secondary schools, local educational agencies, and state educational agencies that receive funds through ED.¹⁵⁰

Evaluation of Complaints

OCR generally uses three factors to evaluate whether a complaint will be investigated. In order for a complaint to be investigated it must:

- Allege a violation of one or more of the laws that OCR enforces;¹⁵¹
- Be timely filed within 180 calendar days of the alleged discrimination, or be granted a request for waiver of the timeliness requirement;¹⁵² and
- Contain sufficient details for OCR to infer that a violation may have occurred.¹⁵³

In addition to these general requirements, OCR may dismiss a complaint after evaluation if its allegations have been resolved;¹⁵⁴ if the complainant's allegations have already been investigated by another federal, state, or local civil rights agency or through a school's internal grievance procedures, including due process proceedings;¹⁵⁵ if its allegations against the school are already being addressed in state or federal court;¹⁵⁶ if the allegations are preempted by federal courts, the U.S. Secretary of Education, ED's Civil Rights Reviewing Authority, or OCR policy determinations;¹⁵⁷ or if OCR is unable to complete the investigation due to difficulty contacting the complainant or lack of cooperation from the complainant or injured party.¹⁵⁸ OCR may also close a complaint if the same allegations have been filed against the same school by someone other than the complainant.¹⁵⁹

Investigation of Complaints

Once OCR opens a complaint for investigation, it issues letters of notification to the complainant and to the complainant's school.¹⁶⁰ During the investigation, OCR serves as a neutral fact finder, evaluating whether there is sufficient evidence that the school has acted in noncompliance with its legal obligations.¹⁶¹ An OCR investigation may include interviewing witnesses, conducting site visits, and reviewing documentary evidence.¹⁶²

Early Complaint Resolution

OCR also has an Early Complaint Resolution (ECR) process designed to facilitate voluntary resolution of disputes as soon as an investigation is opened. Though the agency encourages parties to utilize ECR early in the investigation, ECR may take place at any time during the investigative process.¹⁶³ Both parties must agree to participate and the details of the ECR, including any records related to the process, are confidential.¹⁶⁴ If the ECR is successful, the parties sign a statement indicating that the allegation has been resolved.¹⁶⁵ OCR will then

notify the parties in writing of the resolution.¹⁶⁶ In the event that the ECR is unsuccessful, OCR will proceed with its investigation.¹⁶⁷ Although OCR does not monitor agreements reached between parties in ECR, the complainant may file another complaint with OCR if the school does not comply with the terms of the agreement.¹⁶⁸

Resolution of Complaints

If, after conducting its investigation, OCR determines that there is *insufficient* evidence to determine that the school violated its legal obligations, OCR will issue a Letter of Finding(s) to the parties, which includes:

- A description of the issues raised by the complaint;
- A description of OCR's jurisdiction over the complaint; and
- A discussion of the relevant legal standard and factual analysis.¹⁶⁹

If OCR determines that a preponderance of evidence supports a determination that the school failed to comply with its legal obligations, OCR will attempt to negotiate a Voluntary Resolution Agreement with the school.¹⁷⁰ A Voluntary Resolution Agreement is a written agreement with the school that describes the remedial actions that the school agrees to take to resolve its noncompliance.¹⁷¹ OCR subsequently monitors the school's compliance with the agreement.¹⁷²

If the school does not immediately agree to negotiate a Voluntary Resolution Agreement, OCR gives the school 30 days to state its intent to resolve its noncompliance voluntarily.¹⁷³ If the school fails to so notify OCR, then OCR will issue a Letter of Finding(s) to the parties explaining OCR's legal and factual basis for any finding of noncompliance.¹⁷⁴ Likewise, if negotiations reach an impasse, OCR will issue its Letter of Finding(s) within 10 days of the impasse, unless the parties reach a resolution agreement during that time.¹⁷⁵

Initiating Enforcement Actions

If the school persists in its refusal to voluntarily resolve its noncompliance, OCR issues a Letter of Impending Enforcement Action.¹⁷⁶ If the school still refuses to negotiate an agreement, OCR may suspend, terminate, or refuse to grant federal financial assistance to the school through administrative proceedings, or it may refer the case to DOJ for court proceedings.¹⁷⁷

OCR Complaint Processing System: Statistical Data by Calendar Year

OCR receives thousands of complaints each year.

Total number of complaints received by OCR, by year:¹⁷⁸

2005	2006	2007	2008	2009	2010	2011
5,671	5,771	5,963	6,242	6,637	7,043	1,647

OCR's complaint tracking system does not perfectly align with the inquiry of this report. OCR tracks complaints related to "harassment," which it defines to include both peer-to-peer

harassment as well as harassment of students by staff and third parties.¹⁷⁹ As a result, no mechanism currently exists for isolating data related solely to OCR's work on peer-to-peer incidents.¹⁸⁰ Nevertheless, with this caveat, OCR's data provides an indication of the volume of harassment-related complaints that OCR receives compared to its entire complaint workload, as well as a comparison of the quantity of complaints filed by protected class.

Total number of harassment complaints received by OCR, by year:¹⁸¹

2005	2006	2007	2008	2009	2010	2011
523	527	610	790	774	1,016	193

Race/National Origin

Of those complaints received generally, the following represent complaints related to race or national origin by year:¹⁸²

Calendar Year	2005	2006	2007	2008	2009	2010	2011
Total Number of Complaints Received	2,229	2,251	2,278	1,772	1,919	2,013	346
Black, Not Hispanic	1,006	994	1,076	1,089	1,089	1,197	202
Hispanic	253	255	231	202	233	262	51
Asian or Pacific Islander	79	82	87	74	90	89	8
American Indian or Alaskan Native	45	40	44	56	33	42	7
All of the Above/Class Action	45	54	40	52	130	36	8
Other/Unknown	945	993	940	216	269	332	67
Minority White	67	63	72	53	37	41	5
Non-Minority White	114	117	142	83	77	70	11

Of those complaints based on harassment, the following represent complaints related to race or national origin by year:¹⁸³

Calendar Year	2005	2006	2007	2008	2009	2010	2011
Total Number of Complaints Received	232	231	255	339	361	438	86
Black, Not Hispanic	156	155	173	214	221	273	54
Hispanic	33	31	31	37	43	49	10
Asian or Pacific Islander	16	13	9	21	16	23	2
American Indian or Alaskan Native	10	9	7	15	10	15	3
All of the Above/Class Action	2	2	1	3	1	2	3
Other/Unknown	0	0	1	26	47	57	12
Minority White	10	10	16	11	9	7	1
Non-Minority White	11	13	19	17	14	14	2

Sex

Of those complaints received generally, the following represent complaints related to sex, by year:¹⁸⁴

Calendar Year	2005	2006	2007	2008	2009	2010	2011
Number of Complaints Received	651	659	732	762	824	936	282

Of those complaints based on harassment, the following represent complaints related to sex by year:¹⁸⁵

Calendar Year	2005	2006	2007	2008	2009	2010	2011
Number of Complaints Received	150	153	184	231	220	304	54

Disability

Of those complaints received generally, the following represent complaints related to disability:¹⁸⁶

Calendar Year	2005	2006	2007	2008	2009	2010	2011
Number of Complaints Received	3,447	3,543	3,659	3,847	3,913	4,164	731

Of those complaints based on harassment, the following represent complaints related to disability by year:¹⁸⁷

Calendar Year	2005	2006	2007	2008	2009	2010	2011
Number of Complaints Received	196	193	233	318	284	399	79

Sexual Orientation/Gender Identity & Religion

ED has not historically tracked complaints alleging discrimination based solely on sexual orientation or gender identity, or based on religion.

Because ED does not have jurisdiction to address complaints of discrimination based solely on sexual orientation or gender identity, it has never tracked complaints alleging discrimination or harassment on that basis.¹⁸⁸ When ED has received complaints based solely on sexual orientation or gender identity, those complaints have been closed for lack of jurisdiction without ever being coded as “harassment.”¹⁸⁹ As a result, there is no mechanism for determining how many such complaints OCR has received.¹⁹⁰ Where ED has processed complaints based on sexual harassment or gender-based harassment of LGBT students, those complaints have been tracked as sex-based harassment cases, without distinguishing whether the student identifies as LGBT.

Likewise, because ED does not have jurisdiction to address complaints of discrimination based solely on religion, it has never tracked complaints alleging discrimination or harassment on that basis either.¹⁹¹ When ED receives such complaints, it closes those complaints for lack of jurisdiction without ever coding them for “harassment.”¹⁹² As with harassment based on sexual orientation, there is no means for tracking how many complaints ED has received based solely on religion.

Beginning on October 1, 2010, ED began coding complaints based on “shared ancestry or ethnic characteristics.”¹⁹³ ED has coded 12 complaints alleging discrimination generally based

on shared ancestry or ethnic characteristics.¹⁹⁴ Of those, 5 complaints were coded as racial harassment.¹⁹⁵ Prior to October 1, 2010, when ED processed complaints based on shared ancestry or ethnic characteristics of students that belonged to a religious group, those complaints were tracked as race-based harassment cases, without any reference to religion.¹⁹⁶

While the data collected by OCR does not distinguish between staff-to-student and student-to-student (peer-to-peer) harassment, the Commission was able to extract a small sample of strictly student-to-student harassment for analysis. We obtained copies of all OCR voluntary resolution agreements (and accompanying Letters of Finding) related to harassment issued between 2005 and March 2011. From this set of 292 agreements, we culled 138 related only to peer-to-peer harassment in K-12 schools.

Of the 138 resolution agreements, the following represents the percentage that involved allegations of harassment based on race, national origin, disability, and sex:

Source: Data compiled and analyzed by U.S. Commission on Civil Rights from resolution agreements and associated documents provided by the U.S. Department of Education.

Figure 3.1. Percent of Resolution Agreements Involving Peer-to-Peer Harassment in Elementary and Secondary Schools, 2005 to March 21, 2011, by the Primary Civil Rights Basis.

¹The U.S. Department of Education also negotiated 11 resolution agreements in January to March 2011. They are not included in the figure because they represent only part of the year.

Source: Data compiled and analyzed by U.S. Commission on Civil Rights from resolution agreements and associated documents provided by the U.S. Department of Education.

Figure 3.2. Number of Resolution Agreements Involving Peer-to-Peer Harassment in Elementary and Secondary Schools by Year, 2005 to 2010.¹

The above represents the number of resolution agreements related to peer-to-peer harassment per year, from 2005 to 2010.

The following represents the number of resolution agreements by state, from 2005 to March 2011:

Table 3.1. Number of Resolution Agreements Involving Peer-to-Peer Harassment in Elementary and Secondary Schools by State (Including the District of Columbia), 2005 to March 21, 2011

State	Number	State	Number	State	Number
California	18	Maryland	2	New Hampshire	1
Missouri	17	Michigan	2	New Mexico	1
Illinois	9	Minnesota	2	Rhode Island	1

SECTION 4. FEDERAL ENFORCEMENT EFFORTS: THE U.S. DEPARTMENT OF JUSTICE

The Department of Justice enforces federal statutes that prohibit discrimination in public K-12 schools. Through the Educational Opportunities Section (EOS) of its Civil Rights Division, the Department has opened more than 300 inquiries into complaints of discrimination and harassment from 2001 to April 18, 2011.¹⁹⁷ Beyond responding to complaints, EOS has engaged in a number of activities to address what it has termed a “bullying pandemic,” including participating in an inter-agency taskforce to develop a federal response to bullying in schools, participating in the planning of national bullying summits and a youth summit on a variety of issues facing the LGBT community, including bullying, and conducting community outreach to educate groups on EOS’s jurisdiction and possible collaboration with advocacy groups to assist students who have been subjected to harassment in their schools.¹⁹⁸

Educational Opportunities Section Investigation Process

Generally, EOS enforces laws including Title IV of the Civil Rights Act of 1964, the Equal Educational Opportunities Act of 1974, and Titles II and III of the Americans with Disabilities Act. EOS may also initiate enforcement activities upon receiving a referral from other agencies to enforce Title VI of the Civil Rights Act of 1964, Title IX of the Education Amendments of 1972, Section 504 of the Rehabilitation Act of 1973, and the Individuals with Disabilities Education Act. Further, EOS may intervene in private litigation that alleges violations of the Equal Protection Clause or relevant education-related antidiscrimination statutes as listed above, as well as participate in such litigation as *amicus curiae*.¹⁹⁹ EOS receives complaints by mail, email, telephone, and in person, and it also monitors incidents of harassment through media and other reports. "After an initial inquiry into a complaint, EOS will determine, based on the information available and subject to resource constraints, whether to open an investigation."²⁰⁰ EOS reports that it has not received a referral from ED's Office of Civil Rights since at least 2001.²⁰¹

Available Complaint Information by Calendar Year

Because of its different jurisdictional mandates and complaint/referral mechanisms, DOJ handles far fewer peer-to-peer harassment matters per year than ED. The below data represents those complaints and referrals which resulted in DOJ opening an investigation, as described above. Unlike ED's data discussed above, DOJ's data tracks back to 2001 and attempts to isolate inquiries involving only peer-to-peer harassment.²⁰²

Total EOS opened inquiries:²⁰³

2001	2002	2003	2004	2005	2006	2007	2008	2009	2010	2011
26	22	23	38	29	34	51	29	38	26	6

Total EOS opened inquiries related to peer-to-peer harassment, where such violence may be attributable to the students' race, national origin, religion, disability, or sex:²⁰⁴

2001	2002	2003	2004	2005	2006	2007	2008	2009	2010	2011
4	8	4	14	13	14	33	14	14	5	3

Race/National Origin

Of those complaints received generally, the following represent opened inquiries related to race or national origin by year:²⁰⁵

2001	2002	2003	2004	2005	2006	2007	2008	2009	2010	2011
10	13	11	22	13	14	21	17	23	19	3

Of those complaints received based on peer-to-peer harassment, the following represent opened inquiries related to race or national origin by year:²⁰⁶

2001	2002	2003	2004	2005	2006	2007	2008	2009	2010	2011
2	5	2	6	3	2	13	9	8	4	1

Sex

Of those complaints received generally, the following represent opened inquiries related to sex by year:²⁰⁷

2001	2002	2003	2004	2005	2006	2007	2008	2009	2010	2011
7 (2 SH)	4 (2 SH)	2 (1 SH)	6 (4 SH)	1 (1 SH)	3 (1 SH)	5 (4 SH)	3 (1 SH)	8 (3 SH)	2 (1 SH)	2 (1 SH)

Of those complaints received based on peer-to-peer harassment, the following represent opened inquiries related to sex by year:²⁰⁸

2001	2002	2003	2004	2005	2006	2007	2008	2009	2010	2011
2	2	1	3	1	1	5	3	4	1	2

Disability

Of those complaints received generally, the following represent opened inquiries related to disability by year:²⁰⁹

2001	2002	2003	2004	2005	2006	2007	2008	2009	2010	2011
9	4	3	0	2	4	7	0	5	5	2

EOS did not track peer-to-peer violence based on disability prior to March 2011.²¹⁰

Religion

EOS reports that it tracks complaints related to religion-based harassment separately from harassment based on shared ancestry or ethnic characteristics (i.e., national origin) under Title IV.²¹¹

Of those complaints received generally, the following represent opened inquiries related to religion by year:²¹²

2001	2002	2003	2004	2005	2006	2007	2008	2009	2010	2011
1	3	8	13	14	15	24	13	4	0	0

Of those complaints received based on peer-to-peer harassment, the following represent opened inquiries related to religion by year:²¹³

2001	2002	2003	2004	2005	2006	2007	2008	2009	2010	2011
1	2	3	8	10	11	18	5	3	0	0

Sexual Orientation/Gender Identity

Although EOS does not maintain information on the sexual orientation and gender identity of its complainants, it has opened inquiries into sex-based discrimination based on sex

stereotypes. The Section reports that it opened four such inquiries in 2009, two in 2010, and one to date in 2011.²¹⁴

SECTION 5. THE U.S. DEPARTMENT OF EDUCATION'S DEAR COLLEAGUE LETTER

The U.S. Department of Education issues Dear Colleague Letters as policy guidance under the laws that it enforces. Generally, a Dear Colleague Letter offers guidance to help schools fully understand their legal responsibilities and appreciate the extent of their lawful authority.²¹⁵ It is ED's position that, "when school officials understand their legal duties and the extent of their authority, they are in the best position to prevent peer harassment and to respond effectively when it occurs."²¹⁶ To date, ED has released seven Dear Colleague Letters regarding harassment and three other guidance documents regarding sexual harassment and racial harassment.²¹⁷ The guidance documents range in topic, discussing harassment and bullying generally,²¹⁸ sexual violence,²¹⁹ sexual harassment,²²⁰ disability harassment,²²¹ racial harassment,²²² harassment of Muslim and Arab students,²²³ religion-based harassment,²²⁴ and First Amendment rights.²²⁵ On October 26, 2010, ED issued a Dear Colleague Letter to schools that provided guidance regarding their obligations with respect to bullying and harassment.²²⁶ In addition to outlining schools' general obligations under federal civil rights laws, the Letter provided a series of hypotheticals and advised schools on how best to respond to them. According to Assistant Secretary for Civil Rights Russlynn Ali, while the legal standards discussed in the Letter were not new,²²⁷ the Letter was the "first time ... that Department of Education has put forth such comprehensive guidance on bullying and harassment across all of its statutes. It is the first time that [they] have presented it in these very real-life hypothetical ways."²²⁸

The Letter was intended as a reminder to schools "that some student misconduct that falls under a school's anti-bullying policy also may trigger responsibilities under one or more of the federal antidiscrimination laws enforced by the Department's Office for Civil Rights."²²⁹ ED explained that OCR enforces Title VI of the Civil Rights Act of 1964, Title IX of the Education Amendments of 1972, Section 504 of the Rehabilitation Act of 1973, and Title II of the Americans with Disabilities Act of 1990.²³⁰ It noted, however, that "[w]hile this letter concerns [schools'] legal obligations under the laws enforced by OCR, other federal, state, and local laws impose additional obligations on schools."²³¹ ED said that "harassing conduct" can come in many forms, including verbal acts and name-calling, graphic and written statements (including statements via electronic media such as mobile phones or the Internet), and other conduct that may be physically threatening, harmful, or humiliating.²³² Where the harassment is based on race, color, national origin, sex, or disability, and where such conduct creates a "hostile environment" —i.e., "when the conduct is sufficiently severe, pervasive, or persistent so as to interfere with or limit a student's ability to participate in or benefit from the services, activities, or opportunities offered by a school" —it triggers the civil rights laws enforced by OCR.²³³

The Letter further said that a school must address harassment incidents "about which it knows or reasonably should have known."²³⁴ A school has such notice where "a responsible employee knew, or in the exercise of reasonable care should have known, about the harassment."²³⁵ ED advised that, "[w]hen responding to harassment, a school must take

immediate and appropriate action to investigate or otherwise determine what occurred."²³⁶ The steps of this investigation will differ depending on the circumstances.²³⁷

According to ED, where the investigation shows that unlawful harassment has taken place, "a school must take prompt and effective steps reasonably calculated to end the harassment, eliminate any hostile environment and its effects, and prevent the harassment from recurring."²³⁸ Depending on the circumstances of the harassment, responses can include: "separating the accused harasser and the target"; "providing counseling for the target and/or harasser"; "taking disciplinary actions against the harasser"; providing "training or other interventions ... for the larger school community"; providing "additional services to the student who was harassed in order to address the effects of the harassment"; "issu[ing] new policies against harassment and new procedures by which students, parents, and employees may report allegations of harassment (or wide dissemination of existing policies and procedures)"; or "wide distribution of the contact information for the district's Title IX and Section 504/Title II coordinators."²³⁹ Finally, the Letter advised that the school should take steps to prevent harassment or retaliation against persons who made the initial complaint or assisted the school's investigation: "[a]t a minimum, the school's responsibilities include making sure that the harassed students and their families know how to report any subsequent problems, conducting follow-up inquiries to see if there have been any new incidents or any instances of retaliation, and responding promptly and appropriately to address continuing or new problems."²⁴⁰

When responding to incidents, the Letter advised that obligations under federal civil rights laws are triggered by the "nature of the conduct itself," rather than by the "label used to describe the incident (e.g., bullying, hazing, teasing)"²⁴¹ Furthermore, when these laws are implicated, the Letter encouraged schools to "look beyond simply disciplining the perpetrators [because] the unique effects of discriminatory harassment may demand a different response than would other types of bullying."²⁴²

The Dear Colleague Letter then provided five hypotheticals to illustrate incidents of race, color, or national origin harassment, sexual harassment, gender-based harassment, and disability harassment. After each hypothetical, ED described how the incident would trigger obligations under federal civil rights laws, where the hypothetical school erred in its response, and how the school should have responded.²⁴³

Of note, one of the hypotheticals involved harassment of Jewish students; the Letter said, "[H]arassment against students who are members of any religious group triggers a school's Title VI responsibilities when the harassment is based on the group's actual or perceived shared ancestry or ethnic characteristics, rather than solely on its members' religious practices."²⁴⁴ Another hypothetical involved a student who was gay and who did not conform to masculine stereotypes; the Letter reasoned, "Although Title IX does not prohibit discrimination based solely on sexual orientation, Title IX does protect all students, including lesbian, gay, bisexual, and transgender (LGBT) students, from sex discrimination."²⁴⁵ In the press release issued by ED to announce the Dear Colleague Letter, ED explained that this guidance "makes clear that while current laws enforced by the department do not protect against harassment based on religion or sexual orientation, they do include protection against harassment of members of religious groups based on shared ethnic characteristics as well as gender and sexual harassment of gay, lesbian, bi-sexual, and transgender individuals."²⁴⁶

In closing the Letter, Assistant Secretary Ali wrote, "I encourage you to reevaluate the policies and practices your school uses to address bullying and harassment to ensure that they comply with the mandates of the federal civil rights laws."²⁴⁷

SECTION 6. JURISDICTION: PEER-TO-PEER VIOLENCE RELATED TO LGBT STATUS AND RELIGION

The Departments of Education and Justice have been both lauded and criticized for addressing peer-to-peer student violence related to LGBT youth and members of religious groups.²⁴⁸ Although Title IX grants jurisdiction to ED and DOJ to enforce prohibitions against sex discrimination, it does not mention discrimination based on sexual orientation or gender identity; and although Title VI grants jurisdiction to ED and DOJ to enforce prohibitions against discrimination based on race, color, or national origin, it does not mention discrimination based on religion. Critics have asserted that ED and DOJ's legal interpretations amount to an attempt to "bootstrap" unprotected groups into Titles IX and VI protection.²⁴⁹ This Section will address each issue in turn.

Title IX and Peer-to-Peer Violence Related to Sexual Orientation or Gender Identity

While Title IX does not prohibit discrimination on the basis of sexual orientation,²⁵⁰ its prohibitions against sex discrimination and sexual harassment protect all students, including those who are LGBT or perceived to be LGBT. Title IX also protects against sex discrimination and harassment of students who do not conform to gender stereotypes. Both ED and DOJ enforce Title IX in this regard.

In January 2001, ED issued a document titled *Revised Sexual Harassment Guidance: Harassment of Students by School Employees, Other Students, or Third Parties*.²⁵¹ While the guidance addressed sexual harassment generally, with respect to LGBT students it stated, in part:

Although Title IX does not prohibit discrimination on the basis of sexual orientation, sexual harassment directed at gay or lesbian students that is sufficiently serious to limit or deny a student's ability to participate in or benefit from the school's program constitutes sexual harassment prohibited by Title IX under the circumstances described in this guidance.²⁵²

The guidance further explained that:

[G]ender-based harassment, which may include acts of verbal, nonverbal, or physical aggression, intimidation, or hostility based on sex or sex-stereotyping, but not involving conduct of a sexual nature, is also a form of sex discrimination to which a school must respond, if it rises to a level that denies or limits a student's ability to participate in or benefit from the educational program.²⁵³

ED re-circulated this guidance to schools in January 2006, enclosed with a Dear Colleague Letter issued by then-Assistant Secretary for Civil Rights Stephanie Monroe.²⁵⁴

In September 2008, ED again issued guidance on sexual harassment, which addressed sexual harassment of LGBT students. In a pamphlet titled *Sexual Harassment: It's Not*

Academic, ED posed the question, “Are gay and lesbian students protected from sexual harassment?”²⁵⁵

The pamphlet answered:

Title IX prohibits harassing conduct that is of a sexual nature if it is unwelcome and denies or limits a student’s ability to participate in or benefit from a school’s program, regardless of whether the harassment is aimed at gay or lesbian students or is perpetrated by individuals of the same or opposite sex. *Title IX* does not address discrimination or other issues related to sexual orientation.²⁵⁶

ED once again issued guidance to schools in the Dear Colleague Letter released by Assistant Secretary for Civil Rights Russlynn Ali on October 26, 2010.²⁵⁷ In its discussion of gender-based harassment, ED explained:

Title IX prohibits harassment of both male and female students regardless of the sex of the harasser—*i.e.*, even if the harasser and target are members of the same sex. It also prohibits gender-based harassment, which may include acts of verbal, nonverbal, or physical aggression, intimidation, or hostility based on sex or sex-stereotyping. Thus, it can be sex discrimination if students are harassed either for exhibiting what is perceived as a stereotypical characteristic for their sex, or for failing to conform to gender stereotypical notions of masculinity or femininity. Title IX also prohibits sexual harassment and gender-based harassment of all students, regardless of the actual or perceived sexual orientation or gender identity of the harasser or target.²⁵⁸

Further elaborating on Title IX protections of LGBT students, ED stated:

Although Title IX does not prohibit discrimination based solely on sexual orientation, Title IX does protect all students, including lesbian, gay, bisexual, and transgender (LGBT) students, from sex discrimination. When students are subjected to harassment on the basis of their LGBT status, they may also ... be subjected to forms of sex discrimination prohibited under Title IX. The fact that the harassment includes anti-LGBT comments or is partly based on the target’s actual or perceived sexual orientation does not relieve a school of its obligation under Title IX to investigate and remedy overlapping sexual harassment or gender-based harassment.²⁵⁹

On January 3, 2011, DOJ filed an amicus brief in *Pratt v. Indian River Cent. Sch. Dist.*²⁶⁰ that provided a legal argument for this Title IX analysis.²⁶¹ *Pratt* is an ongoing private civil suit, filed by a student who alleges that he has been targeted for harassment by classmates and school staff because he does not conform to masculine stereotypes and because of his sexual orientation; the student asserts that his school violated his rights under Title IX and the Equal Protection Clause of the Fourteenth Amendment to the U.S. Constitution. The DOJ participated in the case as amicus curiae.

The DOJ based its analysis on two U.S. Supreme Court cases, *Price Waterhouse v. Hopkins*²⁶² and *Oncale v. Sundowner Offshore Svcs., Inc.*²⁶³ Although both cases concerned allegations of sex discrimination under Title VII of the Civil Rights Act of 1964,²⁶⁴ which prohibits discrimination in the employment context, “[c]ourts examine Title VII precedent when analyzing discrimination ‘on the basis of sex’ under Title IX.”²⁶⁵

Price Waterhouse involved the allegation that an accounting firm subjected a female employee to sex discrimination based on evidence that the firm declined to promote her due to her nonconformity with feminine stereotypes. A plurality of the Court concluded that, "[a]s for the legal relevance of sex stereotyping, we are beyond the day when an employer could evaluate employees by assuming or insisting that they matched the stereotype associated with their group"²⁶⁶ It reasoned further, "An employer who objects to aggressiveness in women but whose positions require this trait places women in an intolerable and impermissible catch 22: out of a job if they behave aggressively and out of a job if they do not. Title VII lifts women out of this bind."²⁶⁷ Likewise, agreeing with the plurality in concurrence, Justice O'Connor noted that "[t]here has been a strong showing that the employer has done exactly what Title VII forbids"²⁶⁸

Oncale involved allegations of male-on-male sexual harassment in the workplace. While working on an oil platform, the plaintiff was "subjected to sex-related, humiliating actions," "physically assaulted ... in a sexual manner [and] threatened ... with rape," and "'picked [on] ... all the time ...' and called ... a name suggesting homosexuality."²⁶⁹ The Court found that same-sex sexual harassment is cognizable under Title VII. It held, "[N]othing in Title VII necessarily bars a claim of discrimination 'because of ... sex' merely because the plaintiff and the defendant (or the person charged with acting on behalf of the defendant) are of the same sex."²⁷⁰

In its amicus brief in *Pratt*, DOJ asserted that harassment based on nonconformity with sex stereotypes is a cognizable claim under Title IX and the Equal Protection Clause. To support this statement, DOJ cited *Price Waterhouse*, noting that the Court held that "harassment based on sex stereotyping constitute[s] discrimination on the basis of sex under Title VII."²⁷¹ The DOJ said further that "[t]he standards for proving gender-based harassment under Title VII that were enunciated [by the Supreme Court] in *Oncale* are often cited by courts reviewing similar claims under Title IX."²⁷²

The DOJ then listed several district-court cases that have found claims of harassment based on nonconformity with sex stereotypes to be cognizable under Title IX:

See, e.g., Doe v. Brimfield Grade Sch., 552 F. Supp. 2d 816, 823 (C.D. Ill. 2008) ("Discrimination because one's behavior does not 'conform to stereotypical ideas' of one's gender can amount to actionable discrimination 'based on sex'"); *Riccio v. New Haven Bd. of Educ.*, 467 F. Supp. 2d 219, 226 (D. Conn. 2006) ("The language set forth in the OCR Guidance and the holding in *Oncale* clearly support the conclusion that a female student, subjected to pejorative, female homosexual names by other female students, can bring a claim of sexual harassment under Title IX"); *Theno v. Tonganoxie Unified Sch. Dist. No. 464*, 377 F. Supp. 2d 952, 964-65 (D. Kan. 2005) (recognizing that a gender stereotyping claim may be used to establish that same-sex harassment is based on sex under Title IX); *Montgomery v. Indep. Sch. Dist. No. 709*, 109 F. Supp. 2d [1080,] 1090-93 [D. Minn. 2000] (relying on *Price Waterhouse*, *Oncale*, *Davis*, and the relationship between Title VII and Title IX to hold that the plaintiff had stated a cognizable harassment claim for nonconformity with sex stereotypes under Title IX).²⁷³

The DOJ next stated that the presence of sexual orientation harassment does not defeat a claim of sex stereotyping harassment.²⁷⁴ As the brief explained, "[B]eing gay does not deny a student his right to be free from sex-based discrimination pursuant to Title IX and the Equal Protection Clause."²⁷⁵ In response to the assertion that the sex stereotyping claim is a means of "somehow trying to 'bootstrap protection for sexual orientation' into Title IX," DOJ said that

the U.S. Supreme Court in *Oncale* "cautioned against drawing such superficial, perfunctory conclusions about sex-based harassment"²⁷⁶ It then quoted *Oncale*:

"In same sex (as in all) harassment cases, that inquiry requires careful consideration of the social context in which particular behavior occurs and is experienced by its target. ... The real social impact of workplace behavior often depends on a constellation of surrounding circumstances, expectations, and relationships which are not fully captured by a simple recitation of the words used or the physical acts performed."²⁷⁷

As an example of such "careful consideration," DOJ quoted at length the district court's decision in *Montgomery v. Indep. Sch. Dist. No. 709*:

"Plaintiff contends that the students engaged in the offensive conduct at issue not only because they believed him to be gay, but also because he did not meet their stereotyped expectations of masculinity. The facts alleged in plaintiff's complaint support this characterization of the students' misconduct. He specifically alleges that some of the students called him 'Jessica,' a girl's name, indicating a belief that he exhibited feminine characteristics. Moreover, the Court finds important the fact that plaintiff's peers began harassing him as early as kindergarten. It is highly unlikely that at that tender age plaintiff would have developed any solidified sexual preference, or for that matter, that he even understood what it meant to be 'homosexual' or 'heterosexual.' The likelihood that he openly identified himself as gay or that he engaged in any homosexual conduct at that age is quite low. It is much more plausible that the students began tormenting him based on feminine personality traits that he exhibited and the perception that he did not engage in behaviors befitting a boy. Plaintiff thus appears to plead facts that would support a claim of harassment based on the perception that he did not fit his peers' stereotypes of masculinity."²⁷⁸

Likewise, DOJ also approvingly described the district court's interpretation of *Oncale* in *Riccio v. New Haven Bd. of Educ.* In response to the defendants' assertion that a female plaintiff did not suffer sexual harassment where her ridicule contained anti-gay slurs, the *Riccio* court stated:

"In *Oncale*, the plaintiff was a male being harassed physically and verbally by other males. The derogatory language directed at Mr. Oncale was homosexual in its nature, as in [the plaintiff's] case. Despite the language being of a homosexual nature in *Oncale*, the Supreme Court concluded that the harassment constituted sexual harassment."²⁷⁹

The DOJ concluded, "Because the case law establishes that a plaintiff can concurrently assert claims for sex-based harassment and sexual-orientation-based harassment (even if the latter claims are not cognizable under the same laws), [the plaintiff] should be given an opportunity to prove that the alleged harassment is based on sex under Title IX and the Equal Protection Clause."²⁸⁰

Although ED and DOJ enforce Title IX to protect LGBT students where they are sexually harassed or harassed based on sex stereotyping, a gap remains in their enforcement: federal civil rights law does not protect against harassment based on sexual orientation or gender identity.²⁸¹ Thus, students are not protected by federal law if they are harassed based solely on their sexual orientation or gender identity without accompanying sexual harassment or sex-stereotyping. ²⁸² Such a dichotomy may create a perverse incentive for alleged discriminators

to evade Title IX liability by asserting that students' harassment is based entirely on homophobic animus.²⁸³ Advocates have urged Congress to pass legislation to address this issue²⁸⁴ and, to this end, several relevant bills have been introduced in the 112th Congress. The Student Non-Discrimination Act is designed to address "the significant gap in protection" for LGBT students who, under Title IX, "lack protection against bullying based on sexual orientation."²⁸⁵ In addition, a more general anti-bullying bill, the Safe Schools Improvement Act, enumerates sexual orientation as one of several protected groups.²⁸⁶

Title VI and Peer-to-Peer Violence Related to Religion

Although Title VI does not prohibit discrimination on the basis of religion, it does forbid discrimination on the basis of race, color, or national origin. Both ED and DOJ²⁸⁷ have taken the position that Title VI prohibits discrimination on the basis of actual or perceived shared ancestry or ethnic characteristics, regardless of whether those groups share a common faith.²⁸⁸

On September 19, 2001—eight days after the September 11 terrorist attacks—Secretary of Education Rod Paige issued a Dear Colleague Letter expressing concern about "increasing news reports of incidents of harassment and violence directed at persons perceived to be Arab Americans or of Middle Eastern or South Asian origin, including children."²⁸⁹ Secretary Paige noted that harassment "can take many forms, from abusive name calling to violent crimes directed at a student because of his or her race or ancestry, the country of origin of the student's family, or the student's cultural traditions."²⁹⁰ He continued, "I take this opportunity to highlight our responsibilities under Title VI of the Civil Rights Act of 1964. Title VI prohibits discrimination based on race, color, or national origin by recipients of federal financial assistance."²⁹¹ He further stated:

Racial or ethnic harassment is unlawful. It can deny or limit a student's ability to receive or participate in the benefits, services, or opportunities in a school's program—simply speaking it denies students the right to an education free of discrimination. The existence of a racially hostile environment that is encouraged, accepted, or tolerated by a school, college, or university constitutes different treatment of students on the basis of race.

In response to last week's events specifically, I urge you to make sure that assemblies, classroom discussions, and other school activities held to honor victims of the tragedies do not inadvertently foster the targeting of Arab-American students for harassment or blame.²⁹²

In September 2004, ED issued guidance further elaborating on its enforcement of Title VI with respect to members of religious groups. In a Dear Colleague Letter by Kenneth L. Marcus, then-Acting Assistant Secretary for Civil Rights, ED explained, "Although OCR's jurisdiction does not extend to religious discrimination, OCR does aggressively enforce Title VI, which prohibits discrimination on the basis of race or national origin In OCR's experience, some cases of religious discrimination may also involve racial [or] ethnic ... discrimination."²⁹³ The Letter warned, "[W]e must remain particularly attentive to the claims of students who may be targeted for harassment based on their membership in groups that exhibit both ethnic and religious characteristics, such as Arab Muslims, Jewish Americans and Sikhs."²⁹⁴ It continued:

Groups that face discrimination on the basis of shared ethnic characteristics may not be denied the protection of our civil rights laws on the ground that they also share a common faith.^[295] Similarly, the existence of facts indicative of religious discrimination does not divest OCR of jurisdiction to investigate and remedy allegations of race or ethnic discrimination. OCR will exercise its jurisdiction to enforce the Title VI prohibition against national origin discrimination, regardless of whether the groups targeted for discrimination also exhibit religious characteristics. Thus, for example, OCR aggressively investigates alleged race or ethnic harassment against Arab Muslim, Sikh and Jewish students.²⁹⁶

On September 8, 2010, in a letter from Assistant Attorney General Thomas Perez to Assistant Secretary Russlynn Ali, DOJ endorsed the approach to Title VI outlined in the 2004 Dear Colleague Letter. Asked to address “whether, and under what circumstances, discrimination against persons belonging to discrete religious groups may violate Title VI,” DOJ quoted the 2004 Dear Colleague Letter at length.²⁹⁷

It then concluded:

We agree with that analysis. Although Title VI does not prohibit discrimination on the basis of religion, discrimination against Jews, Muslims, Sikhs, and members of other religious groups violates Title VI when that discrimination is based on the group’s actual or perceived shared ancestry or ethnic characteristics, rather than its members’ religious practice. Title VI further prohibits discrimination against an individual where it is based on actual or perceived citizenship or residency in a country whose residents share a dominant religion or a distinct religious identity.²⁹⁸

ED subsequently issued similar guidance to schools in its Dear Colleague Letter of October 26, 2010. After providing a hypothetical involving anti-Semitic harassment in a middle school, ED explained:

While Title VI does not cover discrimination based solely on religion, groups that face discrimination on the basis of actual or perceived shared ancestry or ethnic characteristics may not be denied protection under Title VI on the ground that they also share a common faith. These principles apply not just to Jewish students, but also to students from any discrete religious group that shares, or is perceived to share, ancestry or ethnic characteristics (*e.g.*, Muslims or Sikhs). Thus, harassment against students who are members of any religious group triggers a school’s Title VI responsibilities when the harassment is based on the group’s actual or perceived shared ancestry or ethnic characteristics, rather than solely on its members’ religious practices. A school also has responsibilities under Title VI when its students are harassed based on their actual or perceived citizenship or residency in a country whose residents share a dominant religion or a distinct religious identity.²⁹⁹

Although ED enforces Title VI with respect to harassment of members of religious groups based on their shared ancestry or ethnic characteristics, Title VI itself leaves a hole in ED’s enforcement. That is, Title VI does not protect against harassment of students based solely on their religious faith, nor does it protect against harassment of students who belong to religious groups that do not have shared ancestry or ethnic characteristics.³⁰⁰ As a result, ED cannot protect students from the “peculiar harms created by religious bigotry.”³⁰¹ Furthermore, under current law, religious groups with shared ancestry or ethnic characteristics receive certain protections that religious groups without shared ancestry or ethnic characteristics do not

receive;³⁰² and would-be discriminators can evade Title VI liability by claiming that students harass based solely on religious bigotry.³⁰³

Advocates urge Congress to close this "loophole" by passing legislation that protects against harassment of students based on their religion.³⁰⁴ Even the current OCR policy, of enforcing Title VI to prohibit harassment of religious groups based on shared ancestry or ethnic characteristics, has not always been followed consistently and may not be followed in the future without a clearer statutory framework.³⁰⁵

Two recent bills before Congress have addressed harassment based on religion. The Safe Schools Improvement Act lists religion as one of several groups enumerated for protection from bullying and harassment.³⁰⁶ And in the 111th Congress, the legislature considered a bill to "amend Title VI of the Civil Rights Act of 1964 to prohibit discrimination on the grounds of religion in educational programs or activities."³⁰⁷

SECTION 7. ADDITIONAL CONCERNS RELATED TO THE FEDERAL RESPONSE

Aside from jurisdiction, concerns regarding the federal response to harassment have focused on enforcement standards, issues of federalism/local control, and the First Amendment.

Enforcement Standards

Some commentators have criticized ED due to the scope of its anti-harassment policy. They contend that the legal standards set forth in ED's Dear Colleague Letter, and elsewhere, are more expansive than the legal standards established by case law.³⁰⁸ The DOJ applies these same standards when it seeks injunctive relief in court. There are three specific standards at issue:

- Notice Requirement. The Dear Colleague Letter instructs that a school "is responsible for addressing harassment incidents about which it *knows or reasonably should have known*."³⁰⁹ This differs from the Supreme Court's statement in *Davis v. Monroe County Board of Education* that schools are liable for damages "only where they are *deliberately indifferent* to [harassment], of which they have *actual* knowledge"³¹⁰
- Hostile Environment, Prong I. The Dear Colleague Letter says that harassment "creates a hostile environment when the conduct is sufficiently severe, pervasive or persistent"³¹¹ *Davis*, however, says that damages are available "only where the behavior is so severe, pervasive, and objectively offensive"³¹²
- Hostile Environment, Prong II. The Dear Colleague Letter further states that a hostile environment exists where, in part, the harassment "interfere[s] with or limit[s] a student's ability to participate in or benefit from the services, activities, or opportunities offered by a school."³¹³ *Davis*, meanwhile, says that a hostile environment requires that the harassment "can be said to deprive the victims of access to the educational opportunities or benefits provided by the school."³¹⁴

ED has defended its notice standard on grounds that, whereas *Davis* involved a private suit for monetary damages, OCR standards are part of their administrative enforcement:

The Supreme Court in *Gebser* [*v. Lago Vista Indep. School Dist.*] and *Davis* was explicit that the liability standards established in those cases are limited to private actions for monetary damages. The Court was concerned with the possibility of a monetary damages award against a school for harassment about which it had not known. In contrast, the process of OCR's administrative enforcement requires OCR to make schools aware of civil rights violations and to seek voluntary corrective action to achieve compliance before pursuing fund termination or other enforcement mechanisms.³¹⁵

Because of this distinction, ED says that it may apply a different notice standard in its administrative enforcement than courts apply in private suits for money damages.³¹⁶

Specifically, ED cites the Supreme Court in *Gebser*, which notes the distinction between standards used in administrative enforcement and private suits for damages:

[T]he failure to promulgate a grievance procedure does not itself constitute "discrimination" under Title IX. Of course, the Department of Education could enforce the requirement administratively: Agencies generally have authority to promulgate and enforce requirements that effectuate the statute's nondiscrimination mandate, even if those requirements do not purport to represent a definition of discrimination under the statute. We have never held, however, that the implied private right of action under Title IX allows recovery in damages for violation of those sorts of administrative requirements.³¹⁷

ED has further stated that the hostile-environment standards it uses are consistent with *Davis*, even if they include different terms:

Although the terms used by the Court in *Davis* are in some ways different from the words used to define hostile environment harassment in OCR's guidance documents, the definitions are consistent. As we explained in our 2001 Sexual Harassment Guidance: "Both the Court's and the Department's definitions are contextual descriptions intended to capture the same concept—that under Title IX, the conduct must be sufficiently serious that it adversely affects a student's ability to participate in or benefit from the school's program. In determining whether harassment is actionable, both *Davis* and the Department tell schools to look at the 'constellation of surrounding circumstances, expectations and relationships,' and the Court in *Davis* cited approvingly the underlying core factors described in the 1997 guidance for evaluating the context of the harassment."³¹⁸

Finally, ED has stated that the standards outlined in the Dear Colleague Letter are not new, but are instead a restatement of standards that OCR has used for nearly 20 years:

They are the same standards that were set forth by OCR in its 1994 guidance on racial harassment, 1997 guidance on sexual harassment, 2000 guidance on disability harassment, 2001 revised guidance on sexual harassment, which was reissued with an accompanying Dear Colleague Letter in 2006, and a 2008 pamphlet on sexual harassment.³¹⁹

Nevertheless, critics have expressed concerns with the standards OCR uses. At the Commission's Briefing on May 13, 2011, one panelist, Professor John Eastman, of Chapman University School of Law, criticized ED's use of standards that differ from *Davis*. He interpreted *Gebser* more narrowly than OCR does,³²⁰ and asserted that "[a]n agency can impose

regulations that are ancillary to the enforcement of a statute authorized by an enumerated power, such as rules requiring the reporting of certain data that is necessary to determine compliance with the underlying statute, but it cannot make up new prohibitions and substantive requirements that are not part of the relevant statute."³²¹ He concluded that "[t]he latitude given to the agencies is narrow, and the deviations between the Department's 'Dear Colleague' letter last October and the reasonable interpretation of the relevant civil rights statute are large"³²² Professor Eastman expressed specific concerns regarding the Dear Colleague Letter's discussions of the notice standard, the kinds of conduct that constitute harassment, and remedial requirements.³²³ Critiques have been made regarding each of OCR's enforcement standards. One criticism, for instance, focuses on the breadth of OCR's notice standard. Critics state that, whereas OCR holds schools accountable for harassment about which they "know or reasonably should have known," this is looser than the *Davis* requirement that schools only be liable for damages for harassment about which they have "actual knowledge" and are "deliberately indifferent." Under this reasoning, OCR's notice standard could, at least in theory, include conduct that a school is not actually aware of, or that it knows about but does not treat with deliberate indifference; under *Davis*, the same school would not be liable for damages in a private suit. OCR, however, has disagreed with this critique, drawing a distinction between retrospective liability addressed in *Davis* and prospective remedies in OCR's administrative-enforcement proceedings.³²⁴ OCR asserts that no school would be punished in such a manner because OCR provides schools with notice of their violation and an opportunity to correct it before it pursues termination of federal funding.³²⁵

Another critique of OCR's standards centers on the first part of the "hostile environment" standard, that the conduct be "sufficiently severe, pervasive, or persistent." By using a disjunctive standard ("or persistent"), OCR might find a single incident to rise to the level of a civil rights violation where it is "sufficiently severe" but not pervasive or persistent.³²⁶ Jocelyn Samuels, of the U.S. Department of Justice, noted this in her testimony to the Commission.³²⁷ This standard differs from the conjunctive *Davis* standard ("so severe, pervasive, and objectively offensive"), which precludes a single incident from triggering damages liability.³²⁸ Critics have said that this difference risks overstepping by the federal government³²⁹ and violations of students' free speech rights,³³⁰ and may misinterpret Supreme Court precedent.³³¹ A second critique of ED's hostile-environment standard has involved the potential breadth of the second prong. Whereas the Dear Colleague Letter states that harassment creates a hostile environment where it, in part, "interfere[s] or limit[s] a student's ability to participate in or benefit from the services, activities, or opportunities offered by a school," *Davis* says the harassment must "deprive the victims of access to educational opportunities or benefits provided by the school." The Foundation for Individual Rights in Education, for instance, criticized the standard's potential breadth in its Public Comment, saying, "This is problematic because 'limit' is a broad term that could encompass effects of widely varying severity, setting a far lower bar for conduct that constitutes harassment."³³²

Others have pointed out that the terms used in the 2010 Dear Colleague Letter's hostile-environment standard differ from those used in previous guidance issued by OCR. Specifically, OCR uses the phrase "interfere with or limit" rather than the phrase from the 2001 Revised Sexual Harassment Guidance, "denies or limits."³³³ Critics claim that the word "interfere"—instead of "deny"—shifts the standard away from the standard in *Davis*. OCR has maintained, meanwhile, that the 2010 definition "is neither new nor inconsistent with *Davis*."³³⁴ Although the words in the 2001 Revised Sexual Harassment Guidance were put forth soon after the *Davis*

decision, and were more similar to the *Davis* standard than previous standards (it changed the previous term, "limit,"³³⁵ to "denies or limits"), ED explicitly stated at the time that it did not intend its 2001 guidance to change its standards in response to *Davis*. Indeed, in its November 2000 Notice of Proposed Revised Guidance, ED said:

[I]n the proposed revised guidance the definition of conduct that creates a hostile environment is substantively the same as in the 1997 guidance, but the discussion contains several revisions to clarify that the *Davis* definition and the guidance definition are consistent. ... Although the terms used by the Court in *Davis* are in some ways different from the words used to define hostile environment harassment in the 1997 guidance, the definitions are consistent. The Court's definition, like the Department's 1997 guidance, is a contextual description intended to capture the same concept—that under Title IX the conduct must be sufficiently serious that it adversely affects a student's ability to participate in or benefit from the school's program.³³⁶

Because insertion of the word "deny" into the 2001 guidance was not intended to alter OCR's standard or match the standard enumerated in *Davis*, replacing the word with "interfere"—a term that had been used to describe the hostile environment standard pre-*Davis*³³⁷—does not necessarily alter the standard either. However, even if the differences between the terms used in OCR's guidance documents are not substantive, this critique highlights that OCR's use of different terms in different documents can be confusing, particularly where it does not explain the changes that it is making. In addition to these targeted critiques, Francisco M. Negrón, Jr., General Counsel of the National School Boards Association, has also offered a broader criticism of OCR's use of stricter standards than those set forth in *Davis*, suggesting that the approach may confuse local school officials. "[N]uanced legal distinctions," he said, "can create confusion that detracts from an understanding of the requirements of the law and could have the unwelcome effect of chilling educators' actions for fear of legal liability under federal civil rights laws."³³⁸ He also feared that The Dear Colleague Letter's standards could lead to additional litigation if courts adopt OCR's standards for private suits that do not involve damages.³³⁹ Mr. Negrón further believed that, while the standards articulated in the Dear Colleague Letter are not new, "[t]he tone of the 2010 [Dear Colleague Letter] is significantly different from that of past guidance."³⁴⁰ Instead of using "a relatively hands-off approach," he reasoned, the 2010 Letter's discussion of examples, mistakes, and remedies "is creating an expectation that school officials are to respond to each and every offensive incident as if it were a civil rights violation."³⁴¹

Federalism

Several commentators have also expressed concerns related to federalism—that is, whether, and in what contexts, peer-to-peer violence is best addressed by states, local school boards, and local officials, rather than by the federal government. In her response to such critiques, Assistant Secretary Russlynn Ali has agreed that "[n]o universal, one-size-fits-all approach will be right for every school or all students"³⁴² She has explained:

[T]he remedies in the [Dear Colleague Letter] may not be required or appropriate in every case. Each case is fact-specific, and OCR will make individual determinations based

on the particular circumstances at a school. The [Dear Colleague Letter] does not change this. ... The DCL does not diminish the importance of administrators' professional judgment; rather it provides examples of appropriate remedies to help inform administrators' decisions.³⁴³

Likewise, at the Commission's Briefing on May 13, 2011, Assistant Secretary Ali said:

[O]ur policy guidance does not attempt to mandate [a one-size-fits-all approach]. Keeping the schools free from harassment is primarily a local responsibility. Teachers' and school administrators' good judgment, common sense, and knowledge of the school community are critical to crafting an effective response to harassment. And parents and community organizations play no less important a role. We therefore encourage and support community-based approaches to addressing peer harassment and changing the school climate so that it does not recur.³⁴⁴

According to Assistant Secretary Ali, "[E]ach school has the ultimate responsibility to create a safe learning environment and to ensure that its policies, practices, and procedures protect all students from discrimination based on race, national origin, sex, and disability. OCR will step in when necessary to ensure that schools fulfill their legal duties."³⁴⁵

When OCR does "step in," she explained, its role can be somewhat limited:

[O]ur administrative enforcement procedures require us to give schools notice of alleged civil rights violations and to seek voluntary corrective action before we can even consider pursuing fund termination or referring the matter to the Department of Justice for litigation. We take full advantage of the opportunity that our procedures afford to educate school officials about their obligations under the civil rights laws, and to help them develop policies to prevent and appropriately respond to harassment.³⁴⁶

Despite OCR's assurances, several critics remain skeptical about the federal government's role in anti-bullying efforts, as well as the use of federal civil rights laws to combat bullying generally.

Some advocates assert that OCR's and DOJ's active roles in combating bullying make it more difficult for schools to address this issue because schools' conduct will be driven by fear of litigation rather than on-the-ground needs. For instance, Francisco Negrón warned that addressing school bullying through civil rights laws at all "will tend to federalize every instance of bullying and harassment by causing school leaders to over-identify every incident of teasing and name-calling as possible harassment."³⁴⁷ Civil rights law, he asserted, "is considerably too blunt an instrument to address the problem of bullying."³⁴⁸ He explained, "What school leaders need, instead of an overly heightened awareness of potential liability and an overly broad definition of bullying, is recognized discretion to exercise professional judgment about the situations on the ground."³⁴⁹ What "[s]chools do not need," however, is "the specter of protracted litigation, money damages, or federal enforcement to inform their choices about school safety."³⁵⁰ He feared that "a school district may adopt, for instance, a more strict enforcement standard following the [Dear Colleague Letter's] guidelines and then somehow adopt for itself some sort of legal liability."³⁵¹

Mr. Negrón and others likewise believed that bullying incidents are most effectively addressed both at the local level and within local schools' discretion. "A bullying incident is best addressed by local entities taking into account the characteristics and priorities of the

communities,"³⁵² he reasoned, and "educators should be free to use whatever tools exist in their professional arsenal to address any conflict between students, including bullying[,which] could mean using the lowest level of intervention necessary."³⁵³ Mr. Negrón suggested that "the first thing we need to do is make sure that our policies empower educators. Educators know that they have the ability to act, to correct whatever situation comes before them, whether it's bullying or harassment."³⁵⁴ "But also," he warned, "we need to not chill their ability to do that. We need teachers not to believe that there will be an impending federal lawsuit if they do not treat a specific set of circumstances as a federal civil rights violation."³⁵⁵

Other critics have averred that the line-drawing involved in anti-bullying efforts—such as determining the distinctions between free speech and unlawful harassment, sex-stereotype harassment and sexual-orientation harassment, and hostile and non-hostile environments—are best left to local authorities.³⁵⁶ As Roger Clegg, President and General Counsel of the Center for Equal Opportunity, stated:

[T]he question is where and how to draw the line and who should draw it. The line-drawing in this area will not always be easy—there are gray areas between argument and teasing and harassment, between threats and horseplay and assault—and certainly the line, even if rightly drawn in theory, will often be crossed by politically correct government bureaucrats in Washington and the lawsuit-shy educators who are intimidated by them.³⁵⁷

"This kind of nuanced line-drawing," Clegg reasoned, "is something where reasonable people can differ, and where people are going to draw the lines differently, depending on local circumstances."³⁵⁸ Panelists also argued that addressing bullying locally, rather than federally, would allow schools to develop and implement a variety of solutions,³⁵⁹ and do so based on local characteristics and individualized circumstances.³⁶⁰

When confronted with these federalism arguments, other advocates responded that active federal involvement in peer-to-peer violence is necessary because, in their experience, localities are failing to adequately address the issue on their own. Eliza Byard, Executive Director of GLSEN, reasoned, if "schools responded when conduct crossed the line into bullying and physical violence, we would not be here today. That is not what is happening. Schools are not responding in a way sufficient to protect the educational access, physical well-being and emotional well-being of young people who are facing violence and harassment every day."³⁶¹

Ms. Byard and others believe that federal intervention is a necessary backstop where local schools and communities fail to act to protect their students, particularly students targeted due to their membership in an unpopular identity group.³⁶² Rajdeep Singh, Director of Law and Policy at the Sikh Coalition, for instance, noted that although New York City has adopted a strong anti-bullying regulation, the policy has not been implemented or enforced effectively.³⁶³ He proffered, "[W]here children's civil rights are being repeatedly violated, and where school officials take a casual approach toward their obligations to protect children from harm, federal intervention becomes a moral imperative."³⁶⁴

Similarly, Helen Gym, of Asian Americans United, discussed her own experiences regarding racial tensions and violence at South Philadelphia High School in Philadelphia, PA, reasoning that federal intervention was necessary to address the conflict. She said, "As appalling as the December 2009 attacks were, it was the egregious conduct of school officials

in the months leading up to that day and in the months following that warranted federal intervention. It is this experience which has shaped our firm belief in the necessity of federal intervention in bias-based harassment at schools."³⁶⁵ She also praised DOJ, which addressed the incident, for its "collaboration with communities to implement at South Philadelphia High School what we hope is a groundbreaking settlement agreement to address bias in schools across the country."³⁶⁶

Although 45 states³⁶⁷ and countless localities have anti-bullying policies, these advocates asserted that the current legal patchwork is inadequate to protect all students nationwide.³⁶⁸

As Paula Goldberg, Executive Director of the PACER Center, said, "[W]e have 45 states that have their own laws, but it is not working. We wouldn't be here today, you wouldn't have this hearing today, if it was working. It's not working. Therefore, we need something consistent."³⁶⁹

First Amendment

Finally, commentators have expressed concerns that ED and DOJ's response to peer-to-peer violence and bullying, and public schools' anti-bullying policies generally, might conflict with protections guaranteed by the First Amendment of the U.S. Constitution.³⁷⁰ Specifically, these concerns involve students' rights to free speech, including religious speech.³⁷¹

According to Assistant Secretary Ali, "very little of the harassment that [ED sees] involves any protected speech."³⁷² She explained:

Physical harassment, violence, and threats are *never* constitutionally protected. Nor is harassment the same thing as unpopular or offensive speech. ... [S]tudent-on-student harassment violates federal civil rights laws only if it is sufficiently serious to create a hostile environment that interferes with or limits a student's ability to participate in or benefit from the services, activities, or opportunities that the school offers. The First Amendment's Free Speech Clause does not give students license to say whatever they want, whenever they want, without regard to the effect of their speech on other students. Schools cannot tolerate discriminatory harassment that interferes with providing a safe, nurturing learning environment for all students.³⁷³

Even when certain speech is constitutionally protected, Assistant Secretary Ali explained, "schools have other means, apart from disciplining wrongdoers, to ameliorate the harms."³⁷⁴ She noted that schools may provide training or other educational programs to teachers, students, and parents, as well as counseling services and medical resources to harassment victims.³⁷⁵

ED acknowledged First Amendment concerns in its Dear Colleague Letter, stating that "[s]ome conduct alleged to be harassment may implicate the First Amendment rights to free speech or expression."³⁷⁶ ED had previously addressed harassment and the First Amendment in a Dear Colleague Letter issued on July 28, 2003.³⁷⁷ The 2003 Letter said that, to implicate federal civil rights laws, alleged conduct must involve more than mere political incorrectness:

Harassment, ... to be prohibited by the statutes within OCR's jurisdiction, must include something beyond the mere expression of views, words, symbols or thoughts that some person finds offensive. Under OCR's standard, the conduct must also be considered sufficiently serious to deny or limit a student's ability to participate in or benefit from the

educational program. Thus, OCR's standards require that the conduct be evaluated from the perspective of a reasonable person in the alleged victim's position, considering all the circumstances, including the alleged victim's age.³⁷⁸

The Letter elaborated:

OCR has consistently maintained that the statutes that it enforces are intended to protect students from invidious discrimination, not to regulate the content of speech. Harassment of students, which can include verbal or physical conduct, can be a form of discrimination prohibited by the statutes enforced by OCR. Thus, for example, in addressing harassment allegations, OCR has recognized that the offensiveness of a particular expression, standing alone, is not a legally sufficient basis to establish a hostile environment under the statutes enforced by OC R.³⁷⁹

The Letter further advised that "schools in regulating the conduct of students and faculty to prevent or redress discrimination must formulate, interpret, and apply their rules in a manner that respects the legal rights of students and faculty, including those court precedents interpreting the concept of free speech."³⁸⁰ It explained, "OCR's regulations and policies do not require or prescribe speech, conduct or harassment codes that impair the exercise of rights protected under the First Amendment."³⁸¹ Likewise, "[t]here is no conflict between the civil rights laws that this Office enforces and the civil liberties guaranteed by the First Amendment."³⁸² ED provided similar guidance in its *Revised Sexual Harassment Guidance* issued in January 2001.³⁸³

Addressing First Amendment implications of alleged discrimination under Title IX, including sexual harassment, ED explained:

Title IX is intended to protect students from sex discrimination, not to regulate the content of speech. OCR recognizes that the offensiveness of a particular expression as perceived by some students, standing alone, is not a legally sufficient basis to establish a sexually hostile environment under Title IX. In order to establish a violation of Title IX, the harassment must be sufficiently serious to deny or limit a student's ability to participate in or benefit from the education program.³⁸⁴

The guidance advised that, "in regulating the conduct of its students and its faculty ... a school must formulate, interpret, and apply its rules so as to protect academic freedom and free speech rights."³⁸⁵

Nevertheless, critics remain concerned. For instance, several advocates have expressed fear that anti-bullying policies could be used by schools and the federal government as a form of viewpoint discrimination. As Hiram Sasser, Director of Litigation at the Liberty Institute, explained, "[t]he rights of students to express their views on issues, even from a religious viewpoint, are clearly established in the law."³⁸⁶ They worried that schools might use anti-bullying policies to unconstitutionally prevent students from expressing their beliefs on issues such as the morality of homosexuality, and that such school practices could be exacerbated by expansive federal intervention. Mr. Sasser, for instance, noted several recent court cases involving schools disciplining students for religious expression at school.³⁸⁷ He said that, "what is really at issue here, is are we going to use the government to stamp out thoughts and beliefs and speech with which the government disagrees."³⁸⁸ Roger Clegg, likewise, said, "I think that part of what's going on here, part of what's being pushed, is an agenda that seeks

to use the power of the federal government to vilify and marginalize people who believe that gay sex is a sin. And they don't want that kind of thought to go unpunished."³⁸⁹ Mr. Sasser worried, similarly, that anti-bullying policies can be a form of government indoctrination,³⁹⁰ and that they may be used by schools to intimidate and harass religious students.³⁹¹

In response to these critiques, several advocates disagreed that the bullying and harassment addressed in ED's Dear Colleague Letter—or even in this report by the Commission—involved constitutionally protected speech; they believed that the viewpoint-discrimination arguments were essentially a red herring.³⁹² “Let me be very clear here,” said Eliza Byard, the words faggot and dyke are not part of any religious creed. And harassment and assault are crimes.”³⁹³ Ms. Byard elaborated that bullying and harassment involves “behavior, not belief,”³⁹⁴ and “ugly speech ... [does] not unto [itself] constitute bullying or harassment. ... There is a context.”³⁹⁵ She further noted that, on the state level, a definition for bullying and harassment has emerged that “includes the concept that the student has a reasonable fear of physical harm, as a result of what they are facing, and even a word as ugly as faggot or dyke ... has to be used in a context where it produces that expectation in a student in order to constitute bullying, or to constitute harassment.”³⁹⁶

Other panelists agreed with Ms. Byard's assessment. For example, Professor Ilan Meyer, of Columbia University, explained:

[N]othing in my testimony [and in others' testimony] is about speech at all. What I was talking about is about schools supporting affirmatively a gay student ... against the types of evidence that I have quoted about being injured, about physical assault, about rape, about being threatened, about having their property stolen, about being threatened with a knife or a weapon. So these are not issues about whether somebody, as Mr. Clegg referred to before, one student thinking it's a sin and another student thinking that it's not a sin.³⁹⁷

Professor Gregory Herek, of the University of California, Davis, concurred:

[W]hat we are talking about is children and youth who aren't simply having a reasoned discussion or disagreeing about a philosophical or religious point. What we are talking about is kids who are feeling that their safety—that they are not safe. They are feeling that they are going to be subjected to physical violence and in fact sometimes have been subjected to physical violence, and that this is something that pervades their life. ... [T]his is something that often ends up being very pervasive and it's something that confronts them on a frequent basis, sometimes on a daily basis, and so that just requires huge amounts of psychological resources to respond to.³⁹⁸

Responding to these assertions that bullying and harassment are not constitutionally protected speech, Professor Eugene Volokh, of UCLA School of Law, disagreed:

I wish that were true, but it seems to me that if you look at what the actual material—for example, the Dear Colleague Letter from the Department of Education says, it really is in considerable measure about speech. That what is labeled bullying and harassment are capacious enough to include speech, including speech that is protected by the First Amendment [I]f you look at the Dear Colleague Letter, it specifically talks about how harassment was defined to include verbal acts. That's lawyer speak for speech or statements.³⁹⁹

Professor Volokh expressed further concerns regarding the risk of over breadth of anti-bullying and anti-harassment policies generally. Noting that a “school might have considerable constitutional authority to restrict such speech if the specific statements pose a substantial risk of materially disrupting the school,”⁴⁰⁰ he warned, there is “[n]o categorical ‘harassment exception’ to the First Amendment.”⁴⁰¹

He asserted: A policy that threatens students with disciplinary action for [speech that creates a “hostile or offensive environment”] is likely to deter a good deal of speech that speakers think *might* be found by the [school] administration to create a “hostile or offensive environment,” and not just speech that is indeed ultimately found (after protracted litigation) to actually create a hostile or offensive environment.⁴⁰²

Professor Volokh also suggested that a First Amendment conflict could exist with respect to the Dear Colleague Letter’s definition of harassment, which does not require the conduct to be directed at a specific target or involve repeated incidents. According to Professor Volokh, “This means that political or religious statements ... could be treated as ‘harassment’ if they are seen as ‘severe’ enough by an administrator, or if they aren’t even severe but are seen as ‘pervasive’ or persistent.”⁴⁰³

Even if the federal government only focuses on harassment that is “the most egregious” and that usually includes violence, Professor Volokh noted, ED and DOJ “also seek[] school policies that are much broader than the particular cases that are the most egregious cases,” and urge schools to stop harassment before it becomes “egregious.”⁴⁰⁴

If “you put all this together,” he reasoned, “there’s a hard to deny First Amendment problem.”⁴⁰⁵

Some public commenters, however, have downplayed many of the First Amendment concerns expressed by Professor Volokh and others where the harassment in question, for instance, disrupts a school’s educational environment, or is discriminatory.⁴⁰⁶ Dean Erwin Chemerinsky, of the University of California, Irvine School of Law, stated in a Public Comment that “[t]he line between protected speech and harassment ... is not settled with regard to schools,”⁴⁰⁷ and where tension does exist, “courts are very likely to defer to the judgment of school officials as to how to best educate their students.”⁴⁰⁸ He reasoned:

Schools may prohibit all conduct, including speech, that constitutes harassment or threats on the basis of characteristics such as race, gender, religion, and sexual orientation. The more speech is simply the expression of ideas, even offensive ideas, the greater the likelihood that it is protected by the First Amendment. However, courts recognize the need for schools to protect their students from harassment and courts are thus likely to be very deferential to school officials in deciding when speech is harassment or threats that can be prohibited and punished. Those who advise the Commission of greater limits on schools, such as in some of the testimony the Commission received, are expressing their views about what they want the law to be; they are not describing the law as it exists.⁴⁰⁹

Similarly, Professor Stuart Biegel, of UCLA Graduate School of Education & Information Studies and UCLA School of Law, stated that “[local] [e]ducation officials have broad power [under the First Amendment] to restrict expressive activity that is reasonably likely to lead to material and substantial disruption or to interference with the rights of others.”⁴¹⁰ He noted that the 7th Circuit has recently “affirmed the right of school officials to draw reasonable boundaries in this area, and ... rejected the notion that First Amendment absolutist arguments should be

controlling in a K-12 education setting"⁴¹¹ with respect to school-climate policies. Professor Biegel quoted an opinion by Judge Richard Posner at length:

"Severe harassment ... blends insensibly into bullying, intimidation, and provocation, which can cause serious disruption of the decorum and peaceable atmosphere of an institution dedicated to the education of youth. School authorities are entitled to exercise discretion in determining when student speech crosses the line between hurt feelings and substantial disruption of the educational mission, because they have the relevant knowledge of and responsibility for the consequences."⁴¹²

In addition to these broad concerns, Professor Volokh and others were also troubled by the Dear Colleague Letter's suggestion that anti-bullying and anti-harassment policies should apply to interactions and statements that occur off-campus, including via email, websites, or social-networking sites.⁴¹³ Describing such policies as "attempt[s] at 24-7 control of student speech,"⁴¹⁴ Volokh reasoned, "[A]ny restrictions on off-campus speech ... would pose especially serious constitutional problems—and, in my view, would be unconstitutional— even if the [school] administration argues that they are 'severe or pervasive' enough to create an on-campus 'hostile or offensive environment.'"⁴¹⁵

ED, in response to such concerns related to off-campus conduct, has asserted that the Dear Colleague Letter does not implicate the First Amendment in this way:

[T]he [Dear Colleague Letter] notes that there are many remedial measures that schools can employ to respond to harassment that cannot be resolved by discipline or otherwise prevented. In some such cases, a school may be able to effectively remedy a hostile environment by, for example, making available counseling services and resources, and educating the school community on civil rights laws and expectations of tolerance—all of which do not implicate the First Amendment.⁴¹⁶

It is clear that the constitutionality of a given school's anti-bullying or anti-harassment policy is complicated, heavily fact-driven, and situation-specific.⁴¹⁷ But for this reason, Professor Volokh concluded that, on First Amendment issues, ED's Dear Colleague Letter is confusing. He did not believe that its mention of the First Amendment in a footnote or reference to prior guidance "suffice[d] to limit the scope of the proposed restrictions, or clarify their vagueness."⁴¹⁸ Instead, he said, the footnote is "not terribly helpful to school districts ... if they need to know what exactly it is that they should be protecting under the First Amendment." Professor Volokh explained:

They're generally not lawyers. Here they have this long letter with all of these examples of mostly conduct, physical violence, that needs to be restricted but also with statements, well, yes, analogous kinds of speech should be restricted, too, and occasional general references to things posted on websites and so on and so forth.⁴¹⁹

He continued:

[The Dear Colleague Letter contains] no meaningful examples of "Here are things that you shouldn't be restricting" or "Here are things that whether or not you should be restricting we don't mean to cover." "Here are the kinds of political or religious or social

or personal commentary on campus or off campus that should be _protected." It just is not offering any real guidance to the school districts. ...⁴"

... [W]hen there's a very big hammer out there, the threat of federal investigation, then that has a disproportionate impact—as opposed to perhaps a threat of a civil lawsuit for vindication of First Amendment rights. So my worry is that with letters like this, approaches like this, that do not really acknowledge the First Amendment issue and don't chart out examples and specific exclusions of what kind of speech should be protected, the inevitable effect is that there will be substantial deterrence of constitutionally protected speech.⁴²¹

While reasonable minds differ on the precise limits of the First Amendment, detailed guidance could indeed be useful to schools as they develop their anti-bullying policies.

FINDINGS AND RECOMMENDATIONS

Findings

- 1) Bullying and harassment, including bullying and harassment based on sex, race, national origin, disability, sexual orientation, or religion, are harmful to American youth.
[Commissioners Castro, Thernstrom, Achtenberg & Yaki voted in favor; Commissioners Gaziano, Heriot & Kirsanow voted against; Commissioner Kladney abstained.]
- 2) Current federal civil rights laws do not provide the U.S. Department of Education with jurisdiction to protect students from peer-to-peer harassment that is solely on the basis of religion.
[Commissioners Castro, Thernstrom, Achtenberg & Yaki voted in favor; Commissioners Gaziano, Heriot & Kirsanow voted against; Commissioner Kladney abstained.]
- 3) Current federal civil rights laws do not protect students from peer-to-peer harassment that is solely on the basis of sexual orientation.
[Commissioners Castro, Thernstrom, Achtenberg & Yaki voted in favor; Commissioners Gaziano, Heriot & Kirsanow voted against; Commissioner Kladney abstained.]

Recommendations

- 1) The U.S. Departments of Education and Justice should track their complaints/inquiries regarding peer-to-peer harassment separately from complaints/inquiries regarding staff-to-student harassment.
[Commissioners Castro, Thernstrom, Achtenberg & Yaki voted in favor; Commissioners Gaziano, Heriot, Kirsanow & Kladney abstained.]
- 2) The U.S. Departments of Education and Justice should track their complaints/inquiries regarding sexual harassment or gender-based harassment by creating a category that explicitly encompasses LGBT youth.

- [Commissioners Castro, Thornstrom, Achtenberg & Yaki voted in favor; Commissioners Gaziano & Heriot voted against; Commissioners Kirsanow & Kladney abstained.]
- 3) The U.S. Departments of Education and Justice should track complaints that they receive regarding harassment based solely on sexual orientation that are closed for lack of jurisdiction.
[Commissioners Castro, Thornstrom, Achtenberg, Gaziano, Heriot, Kirsanow, Kladney & Yaki voted in favor.]
- 4) The U.S. Department of Education should track complaints that it receives regarding harassment based solely on religion that are closed for lack of jurisdiction.
[Commissioners Castro, Thornstrom, Achtenberg, Gaziano, Heriot & Yaki voted in favor; Commissioners Kirsanow & Kladney abstained.]
- 5) The U.S. Department of Education should consider issuing a new Dear Colleague Letter regarding the First Amendment implications of anti-bullying policies. The new Letter should provide concrete examples to clarify the guidance that the Department of Education previously provided in its Dear Colleague Letter on the First Amendment dated July 28, 2003.
[Commissioners Castro, Thornstrom, Achtenberg & Yaki voted in favor; Commissioners Gaziano, Heriot & Kirsanow voted against; Commissioner Kladney abstained.]
- 6) The U.S. Department of Education should strive to use consistent language when it articulates legal standards, such as its enforcement standards, in its Dear Colleague Letters and guidance documents. When the Department of Education uses different, even if consistent, terms in its Dear Colleague Letters and guidance documents, it should explain the reasoning behind its use of different wording.
[Commissioners Castro, Thornstrom, Achtenberg, Gaziano, Heriot, Kirsanow, Kladney & Yaki voted in favor.]

COMMISSIONER STATEMENTS AND REBUTTALS

Statement of Chairman Martin R. Castro

"Bullying can have destructive consequences for our young people and it's not something we have to accept. As parents and students, as teachers and members of the community, we can take steps—all of us—to help prevent bullying."

--President Barack Obama

March 2011

Introduction

President Obama is right: We all can do something to prevent the destructive consequences of bullying. That is why I am proud that this briefing on "Peer-to-Peer Violence and Bullying" is the first briefing I conducted as Chair of the Commission. As I said at the briefing, this is an extremely important issue for us all. Every one of us has children in our lives that we love and care for, whether they are our own children, grandchildren, nieces, nephews, students, godchildren, or neighbors. We all want those children to have safe, happy, and long lives and

reach their full potential. Not only is this a personal desire, but I also believe it is a civil and human right.

As I also stated at the briefing, I know that each of us, regardless of our Party affiliation or our political ideology, wants to have communities and schools that are safe for our children, regardless of their race, national origin, sex, religion, disability status or sexual orientation. Where we may differ is how to accomplish that goal. I hope that this Statutory Enforcement Report is viewed as a constructive contribution to the discussion on how our Constitution and laws do and *should* protect the most vulnerable among us—our children.

I want to thank our staff, especially our Office of the General Counsel, for their extraordinary work in the organization of the briefing and the preparation of our Report. I also wish to commend my fellow Commissioners for the bi-partisan manner in which we conducted the briefing and for the fact that we were even able to promulgate some findings and recommendations unanimously. I also wish to thank our distinguished panelists and all of those individuals and organizations that provided voluminous written testimony to the Commission. While every submission may not be included in the Report, every submission was important to our effort to address this important issue.

I am very proud of the Report. This Statement will highlight some points I consider to be of special importance.

Why Is the Commission Concerned About Peer-to-Peer Violence and Bullying?

When student violence, harassment or bullying is motivated by race, national origin, religion, disability, gender, gender identity and gender stereotypes, it falls within the Commission's mandate to shine a light on the issue in an effort to remedy the wrong. As the Third Circuit Court of Appeals said in the *Sypniewski* case, "there is no constitutional right to be a bully."¹

While the Report contains a "disclaimer" that some "critique the usefulness or accuracy" of data presented by state and federal agencies, academics and interests groups about the scope of the bullying problem, there can be no doubt that what is being reported in the data is real—that our youth are being bullied on the basis of race, national origin, disability, gender, religion, or sexual orientation. Whether the number of students is in the tens of thousands or hundreds of thousands is certainly fertile ground for further empirical studies, but no one should be able to deny that this is a problem in the United States.

During our briefing, in the written submissions, and in virtually daily news accounts, we see uncontroverted evidence that American youth are being bullied, harassed and having violence perpetrated against them by their peers, in whole or in part, because of their membership or perceived membership in certain protected or demographic classes. When that happens, I believe the Federal government has an important role to play. I applaud the U.S. Departments of Justice and Education for their efforts to address these types of cases of bullying, violence and harassment. That is why I also am a strong proponent of giving them the additional jurisdiction they need to fully address the instances of the type of conduct that infringe on students' Constitutional rights to life, liberty and happiness.

While there are 45 states with anti-bullying laws, the current state-level anti-bullying laws neither protect all students nationwide nor provide all students with equal and consistent levels of protection from state to state. As our Report points out, existing federal laws leave loopholes

that do not protect students who are being bullied solely because of their religion or sexual orientation. Therefore, I believe Congress should enact and the President should sign into law both the Safe Schools Improvement Act and the Student Non-Discrimination Act. In addition, Congress should amend Title VI to prohibit discrimination on the basis of religion and the President should sign such a bill into law. These laws will close loopholes and give federal agencies the tools they need to fully and equally protect students when and where state laws or school districts can't or won't.

A Comprehensive, Consistent Approach Is Needed

However, we cannot merely legislate and litigate these issues away. We must also educate and train. Only through a holistic approach can we ever hope to overcome the destructive consequences of peer-to-peer violence, harassment and bullying.

That's why I support the thoughtful recommendations of organizations such as the American Bar Association ("ABA"), the National Education Association ("NEA"), the Anti-Defamation League, and others, which call for the regular training of administrators, teachers and students in how to identify and respond to instances of bullying.

I applaud the NEA for providing free anti-bullying training through its National Bullying and Sexual Harassment Prevention and Intervention Program and for incorporating anti-bullying strategies into its school transformation campaign.

Furthermore, as the ABA points out in its Report in support of its anti-bullying Resolution of February 14, 2011:

“Effective anti-bullying programs are known to include the following: ‘target known risk factors in youth violence; involve youth, parents, teachers and community members; monitor the implementation of the program components; use culturally-relevant, gender-specific and developmentally appropriate strategies; establish high standards and expectations for staff and participants; and provide comprehensive and ongoing interventions.’”²

I also agree with the ADL's recommendation regarding the interrelationship of the enforcement of anti-bullying efforts and the Matthew Shepard and James Byrd, Jr. Hate Crimes Prevention Act.³

This type of comprehensive approach, coupled with strong federal anti-bullying protections will help to holistically begin to address this problem.

Culturally and Linguistically Appropriate Protections for Limited English Proficient Persons

It is difficult enough to discern whether your child is the victim of bullying, harassment or violence at school, let alone know what your rights are and how to navigate the system to enforce them and protect your child. Now imagine trying to do all of this with limited English language proficiency and/or cultural barriers. In addition, students with language barriers may also find it more challenging to report incidents of bullying, harassment or violence, or suffer a chilling effect in reporting these situations to a school system that is not linguistically or culturally accessible. For example, as Ms. Helen Gym of Asian Americans United testified at our briefing regarding the violence perpetrated against Asian students in Philadelphia: “Staff members... failed to investigate reported complaints, or worse, refused to file incident reports unless students spoke English to them, and who failed to call for translation assistance for

concerned parents and families.”⁴ Ms. Gym further testified, “The district failed to translate documents or provide students and families with interpretation. Students reported that school security did not offer translation assistance to students who made complaints, and therefore, did not investigate them, or only heard the perspective of the English-speaking student.”⁵

Therefore, school districts should provide to Limited English Proficient student victims and their families information in their respective languages about how to report incidents of violence, harassment and bullying, and how to enforce their rights under existing district policies and applicable state and federal laws. School districts should also make reasonable efforts to have spoken-language translators available to students and families to assist in this dissemination of information and in the accurate reporting of complaints of bullying, violence or harassment. It is not just enough to have bilingual staff. The staff must be trained in interpretation and be knowledgeable about the anti-bullying policy of the school. As the ABA states in its report, “Without taking into consideration the cultural and linguistic differences among youth, it is unlikely that any [anti-bullying] program will be successful.”⁶

Neutrality Policies Are Anything But Neutral

“Neutrality” policies in schools require staff to take a neutral position when it comes to matters of sexual orientation in the school’s curriculum. However, in practice, these neutrality policies, also known as Sexual Orientation Curriculum Policies, are being erroneously applied in areas beyond curriculum, with devastating results, as we heard from Tammy Aaberg. Ms. Aaberg was the mother of Justin, a 15 year old who committed suicide last year after experiencing bullying and harassment due to his sexual orientation. When it was reported to Justin’s school, which had a neutrality policy, the school allegedly failed to take action because, as his mother testified, the neutrality policy “confuses teachers and staff and they feel like their hands are tied, as they don’t know what should or shouldn’t be considered neutral. I believe this is what happened with the Counselor. Once she heard the word gay, she didn’t ask Justin’s friend any further questions and I never received a phone call.”⁷ The results were tragic for the Aaberg family. We should not allow this tragedy to continue to be repeated in schools across the country.

While Ms. Aaberg presented her story, the story of one family, of one child, that should not diminish the impact of her request for help for other children like Justin who are persecuted solely because of their sexual orientation. Or for that matter, for other students who are also bullied, harassed and have violence perpetrated against them because of their race, national origin, gender, disability or religion. Therefore, school districts should rescind these neutrality policies that lead to instances of bullying, harassment and violence going unaddressed.

I was very moved by Ms. Aaberg’s testimony about the loss of her son. I believe her words best summarize why we must take every step possible to ensure that existing laws are enforced fully, and new laws enacted to protect ALL of our children:

“These children are dead, my son is dead. Justin is gone from this earth and I will never be able to give him a hug, see his smile, hear his beautiful Cello playing or tell him I love him. Because some people believed he deserved fewer protections than others. All of these children and too many others across the country all died too young as a result of bullying and harassment.”⁸

It is time for us to make certain that our Constitution and laws are interpreted and enforced in a manner that provides the necessary protections against bullying, harassment and violence inflicted on students on the basis of their race, national origin, gender, disability religion or sexual orientation—for all of our children's sake.

Statement of Vice Chair Abigail Thernstrom

Data

I am disturbed by the self-reported nature of the data presented in this report. Perceptions of discrimination are not reality. Of course the testimony of people who believe they have been victims must be taken seriously, but it is essential to verify those claims. They do not accurately register the frequency of incidents unless we are willing to say, if you feel you have been bullied, you have been bullied.

In addition, the data upon which we relied were, in many cases, collected by advocacy organizations with a clear agenda; again, the numbers need verification. Some of these organizations characterize conduct as “harassment” that doesn’t qualify as such under federal law. Readers should take definitional problems into account when looking at questions of how federal agencies enforce anti-harassment laws.

School Culture

Before moving on to other concerns I have with the report, I should say, as a preliminary matter, that I do not believe that controlling unacceptable student behavior in schools is – as the cliché runs – rocket science. I have spent much time in both orderly and disorderly schools. In those that are well run and have a culture truly devoted to education, no student even thinks of harassing peers or teachers – the latter often being a serious problem. The inmates do not run the asylum where there are clear messages about who is in charge, and about acceptable and unacceptable behavior. In orderly, disciplined schools, there is no running in the halls, fights between students, disrespectful language used in talking to other students or to teachers.

The secret to creating such schools is very simple: The messages about expectations with respect to behavior and language are communicated by every teacher in every setting, and by administrators as well. No principal locks himself or herself behind a closed door, letting bedlam occur out of sight and thus out of mind. Students face consequences when they are late to school, when food is thrown in the lunchroom, when they dress in a slovenly manner, when they use their fists to settle disagreement, and when their language violates rules of respect and self-respect. Slovenly language and slovenly dress are like James Q. Wilson’s famous “broken windows” in a city. If not repaired, they send a signal that no one cares about disorder, and that signal is a slippery slope to a community in which fear is ever-present.

Why don’t more schools – particularly those in the inner city – fit the description above? In too many schools, civility is not regarded as integral to education. It should be seen as equally, if not more important, than the three Rs. A student’s employment prospects in life will depend on it. And yet often teachers and administrators with whom I have discussed the importance of a school culture tell me that they would be imposing middle class values on their students if they listened to me – although “middle class” jobs are precisely that they should be making their disadvantaged students eligible for.

A Federal Fix?

School culture is something that only schools can set. Values cannot be imposed from above or outside. It is very difficult to see how the federal government can play a major role in stopping bullying in hundreds of thousands of schools across the land. As one of our witnesses, Dr. John Eastman testified,

There are lots of problems in society that are beyond the authority of the national government to address. The kinds of interactions between children on school playgrounds that have existed since we had schools would seem to be near the top of the list. And even if we could find constitutional authority for the federal government to intervene in this quintessentially local setting, do we really think that bureaucrats in Washington, D.C. should be crafting a national, one-size-fits-all policy on how to manage the interactions of children on the playground?¹

First Amendment Issues

Witnesses at the briefing explored other important issues. For instance I have First Amendment concerns that would arise with federal intervention regulating student speech, even when that speech is perceived as harassment. Here is an issue on which perhaps there can be consensus. I hope we can all agree that *"a school must formulate, interpret, and apply its rules so as to protect academic freedom and free speech rights,"* as the OCR Guidelines of January 19, 2001 stated.²

In addressing the First Amendment question, panelist Eugene Volokh cited the Supreme Court's *Davis v. Monroe County Board of Education* decision³ that "suggests that Title IX (and, by extension, Title VI) [did] require schools to ban certain forms of harassment." It was a case, however, that involved "physical touching and unwanted vulgar sexual references," he noted. Prof. Volokh was thus not sure "its holding would apply in a case based on politically or religiously themed speech." Moreover, he noted, "liability could only be imposed "where the behavior [was] so severe, pervasive, and objectively offensive that it denie[d] its victims the equal access to education . . ." Volokh concluded:

schools should be encouraged to craft policies in terms such as these, rather than using terms such as "bullying," "harassment," or the creation of a "hostile or offensive environment" through "severe or pervasive" conduct.⁴

Religion

While the scope of our report included student-on-student harassment and bullying based on religion, Congress has not enacted legislation to prohibit religious discrimination in programs and activities which receive federal funds such as public schools and colleges. Title VI of the Civil Rights Act of 1964 prohibits discrimination based on race, color, and national origin. Subsequent legislation also prohibits discrimination based on sex, disability, and age. But there is no law prohibiting religious discrimination by recipients of federal funds.

However, over the years OCR has issued policy guidance regarding discrimination based upon shared ancestry or ethnic characteristics which may overlap or coincide with a victim's religious practices or beliefs. The most recent such guidance was contained in OCR's Oct. 26, 2010 "Dear Colleague" letter:

While Title VI does not cover discrimination based solely on religion, groups that face discrimination on the basis of actual or perceived shared ancestry or ethnic characteristics may not be denied protection under Title VI on the ground that they also share a common faith.⁵

Since this protection is articulated in a guidance document it may not survive changes in administrations, does not have the same force as law, and only indirectly protects against religious discrimination. Moreover, the discrimination must be based on “perceived, shared ancestry or ethnic characteristics” of a religious group.⁶

Insofar as bullying and harassment based on enumerated protected characteristics is a problem requiring federal intervention in our local schools – and I’m not certain that is the case – Congress might consider enacting legislation specifically prohibiting religious harassment and discrimination in federally funded education programs.

Statement of Commissioner Roberta Achtenberg

Introduction¹

The breadth and depth of the record in this inquiry demonstrate that students target each other for peer-to-peer bullying, harassment, and violence due to identity-based animus, all too frequently. The numerous, complex short and long-term negative consequences of such victimization underscore the urgency of careful monitoring, proactive intervention, and access to enforcement of rights by targeted students and their families.

Each demographic class of students examined -- those identified by race or national origin, sex, disability, sexual minority or gender non-conforming youth status, or religion -- suffers a serious and pervasive level of victimization. Needless to say, all children deserve to be protected from such targeting so that they may learn and grow in safety, regardless of what negative beliefs may persist about their status or identifying characteristics.

I concur with each of the Findings and Recommendations contained in the body of the U.S. Commission on Civil Rights’ 2011 statutory enforcement report, “Peer-to-Peer Violence and Bullying: Examining the Federal Response”² This Statement puts forth the additional findings and recommendations that I believe the multi-faceted and credible record supports.

Findings

Finding #1: Peer-to-peer violence, bullying, and harassment based upon animus toward students’ race, national origin, sex, religion, disability, and/or sexual orientation or gender non-conformity occur at high rates. These actions constitute serious and pervasive problems which negatively affect schools, students and their families.

The USCCR Report finds first that “[b]ullying and harassment, including bullying and harassment based on sex, race, national origin, disability, sexual orientation or religion, are harmful to American youth.” This is an important conclusion drawn from the Commission’s inquiry. Yet, it does not go as far as the record supports to underscore the severity of the underlying problems. In view of the depth and breadth of the Commission’s record, it is appropriate to characterize the scope of the problem in more serious terms, as well as to make more particularized findings and recommendations.

Finding #2: Up to one-quarter of racial and ethnic minority students are targeted for peer-to-peer bullying, harassment, and violence.

The numbers of complaints alleging race-based harassment made to the U.S. Department of Justice and the U.S. Department of Education demonstrate the continuing seriousness of the problem. Complaints alleging racial or national origin discrimination represent a significant percentage of overall complaint statistics in each of the years that the Commission examined, 2005 through 2011. In some years, more complaints alleging racial or national origin harassment were made than those asserting that other types of animus-based harassment had been perpetrated.³ As the USCCR Report notes,

[t]he California Healthy Kids Survey conducted in 2007-2009 found that when youth in California were bullied or harassed on school property, the most common specific reason cited was because of their race or national origin, with about 18 percent of students in grades 7, 9, and 11 reporting at least one bullying incident in the past year for this reason. The problem is not limited to one specific racial or ethnic group. When results from 9th and 11th grade students are broken down by race and ethnicity, African-American students reported being bullied or harassed due to their race or ethnicity at the highest rate — 23 percent. Twenty-two percent of Asian-American students, 22 percent of Native Hawaiian or Pacific Islander students, and 20 percent of Native American students reported being harassed due to their race, ethnicity, or national origin as well. [citations omitted].⁴

Finding #3: Disabled students are at significantly higher risk of targeting for peer-to-peer bullying, harassment, and violence than are non-disabled students.

As the USCCR Report indicates, “[t]hough research regarding the connection between bullying and disability is fairly limited ..., such research seems to indicate that students with disabilities are two to three times more likely than students without disabilities to be victims of bullying.”⁵ The paucity of studies in this area is of particular concern in light of the wide range of physical and mental health disabilities which affect students⁶ and the differing ways in which peer-to-peer student bullying, harassment, and violence pertain to each, and in view of the fact that “[t]he limited research on bullying in special education has indicated that special education students are more likely to be victimized.”⁷ Specifically with regard to students with learning disabilities, there has been:

very little research [citations omitted]. ... [However, b]ased on the research to date and on the characteristics common to children with [learning disabilities] and children who are bullied, there is reason to believe that children with [learning disabilities] are at greater risk of peer victimization [citations omitted].⁸

This is of particular concern where “the co-occurrence of peer victimization and [learning disabilities] for children and youth may have separate and additive effects, substantially heightening these children’s chance of experiencing social and emotional problems [citation omitted]....”⁹ Disabled students’ heightened risk of being targeted has been demonstrated with regard to students with Attention Deficit Hyperactivity Disorder (hereinafter “ADHD”). Specifically:

[m]iddle-school students who reported taking medications for ADHD were ... more likely to report being bullied [than students not taking such medication]. ... 34% of the

students who reported taking ADHD medication, in comparison to 22% among other students, reported that bullies victimized them at least 2 or 3 times a month.¹⁰

Also, the Commission has learned that:

[i]n a 2009 study of parents of children with Asperger Syndrome, 94 percent reported that their children had been bullied. [citation omitted.] Additionally, 65 percent reported that their children had been victimized by peers within the past year, while 50 percent reported that their children were scared by their peers.¹¹

Finding #4: Over three-quarters of all students experience sex-based bullying, harassment, or peer-to-peer student violence.

As the USCCR Report indicates, “statistics on sex-based bullying in K-12 schools are somewhat limited.”¹² Nonetheless, the USCCR Report presents good data from the Commission’s record. Specifically,

a 2001 study by the American Association of University Women (AAUW) found that 81 percent of students in grades 8 to 11 reported experiencing sexual harassment, including 83 percent of girls and 79 percent of boys. Twenty-seven percent of the students surveyed, including 30 percent of girls and 24 percent of boys, said that they were sexually harassed often. Seventy-six percent of students reported that they experienced nonphysical harassment often, occasionally, or rarely, while 58 percent reported experiencing physical harassment often, occasionally, or rarely. And 44 percent of girls and 20 percent of boys reported that they were afraid of being sexually harassed at school. [citations omitted.]

In addition, in the School Survey on Crime and Safety (SSOCS), sponsored by the U.S. Department of Education’s National Center for Education Statistics, schools reported 800 incidents of rape and 3800 incidents of sexual battery not involving rape in the 2007-2008 school year. The AAUW study found that 12 percent of boys and 9 percent of girls in grades 8 to 11 reported that they had been forced to do something sexual other than kissing. [citations omitted.]¹³

Finding #5: Students of different religions, including Sikhs, Jews, Muslims, and Christians, report being targeted for bullying, harassment, or peer-to-peer student violence. For example, rates of Sikh student victimization range from roughly half to over three-quarters.

Issues of the targeting of students for peer-to-peer bullying, harassment, and violence based upon religious animus raises civil liberties issues that are a bit more complex than the victimization of students in other classes. As panelist Kenneth Marcus testified,

[i]ntuitively, one would expect children victimized by religious hate to enjoy the apex of protections afforded under our constitutional system. Structurally, they are victimized at the convergence of the First and Fourteenth Amendments, denied not only the Constitution’s “first freedom” [citation omitted] but also the very interest in equal educational opportunity that has been constitutionally preeminent since *Brown v. Board of Education*. [citation omitted].¹⁴

Unfortunately, in this era of escalating religious intolerance, such legal subtleties are not being observed in the nation’s classrooms. According to a study of youth survey data in California, 9.1% of students report being targeted for peer-to-peer harassment due to their religion.¹⁵ By way of illustration, the Report demonstrates that, in addition to Muslim,

Christian, and Jewish students, Sikh students in the United States are targeted for animus-based peer-to-peer problems. Of particular note,

[a] 2010 survey by the Sikh Coalition, conducted in the San Francisco Bay Area in California, found that 47 percent of local Sikh youth were subjected to bullying. Of the boys who wear turbans (or patkas), 74 percent reported being subjected to bullying. The survey found bullying to be most prevalent in Alameda County, where 86 percent of Sikh boys reported being targeted. Likewise, a 2007 Sikh Coalition survey of Sikh youth in New York City found that 58.4 percent of local Sikh students had been subjected to bullying. The survey found that 62.2 percent of boys who wear turbans (or patkas) reported that they were bullied and 42 percent reported being physically hit or involuntarily touched. In the borough of Queens, as high as 77.5 percent of boys reported being bullied. [citations omitted.]¹⁶

Finding #6: Data shows that forty to fifty percent (40 to 50%) of sexual minority and gender non-conforming youth are targeted for peer-to-peer bullying, harassment, or violence.

Leading institutions and researchers, including the Institute of Medicine of the National Academies, have recognized that peer-to-peer bullying, harassment, and violence against sexual minority and gender non-conforming youth is so serious and pervasive as to constitute a public health problem of the highest order.

The recent report of aggregated data by the Institute of Medicine concluded that “[c]ompared with heterosexual youth, LGBT youth report experiencing higher levels of harassment, victimization, and violence, including verbal, physical, and sexual abuse.”¹⁷ The recent work of Dr. Mark Friedman of the University of Pittsburgh¹⁸ is also a relevant aggregation of studies. Dr. Friedman’s meta-analysis “included only studies that compared sexual minority and sexual non-minority (heterosexual) youth.”¹⁹ Further, and critically, his work “included ... only school-based studies that used probability (sometimes referred to as random) samples of youth. That is, youth assessed in these studies represent the populations of youth attending high schools in the communities where the studies were conducted.”²⁰ Simply put, Dr. Friedman’s work is a meta-analysis of probability studies. Its relevant conclusions should, therefore, be assigned particular validity and credibility. Dr. Friedman concludes that his “research, using state of the art methodology, has confirmed that bullying victimization of sexual minority youth (i.e., youth who are sexually attracted to same-sex youth, self-labeled as gay, lesbian or bisexual) is a major public health problem.”²¹ Dr. Friedman found that much peer-to-peer bullying, harassment, and violence toward sexual minority and gender non-conforming youth tends to be expressed through physical violence. Specifically,

[o]ver the aggregate of all the studies that qualified to be included in the meta analysis, compared to heterosexual youth, ... [s]exual minority youth were 170% more likely to be assaulted at school”²² and that “40% of lesbians 44% of bisexual females, 43% of gay males and 50% of bisexual males were assaulted at school....”²³

Finding #7: Sexual minority and gender non-conforming youth do not have an intrinsically heightened vulnerability to negative outcomes from peer-to-peer bullying, harassment, and violence. Rather, ongoing societal stigmatization of homosexuality, as opposed to any inherent weakness, makes these youth particularly susceptible to negative outcomes resulting from identity-based harassment.

Homosexuality has long been understood to be a normal variation of human sexuality.²⁴ A cornerstone of this knowledge is the fact that the American Psychiatric Association (APA) concluded almost forty years ago, in 1973, that "homosexuality in and of itself implies no impairment in judgment, stability, reliability, or vocational capabilities,"²⁵ and that "homosexuality is not considered a mental disorder in APA's Diagnostic and Statistical Manual, Fourth Edition (DSM-IV-TR)."²⁶

The American Psychological Association expressed its support for the American Psychiatric Association's change in viewpoint in 1975.²⁷ A wide array of professional mental health groups have subsequently endorsed the position that homosexuality is normal, as evidenced by their support for the American Psychiatric Association's recommendation against "any psychiatric treatment, such as 'reparative' or 'conversion' therapy, that is based upon the assumption that homosexuality per se is a mental disorder or is based on the a priori assumption that the patient should change his or her homosexual orientation."²⁸

Numerous studies, both meta-analyses and individual investigations, have demonstrated that sexual minority and gender non-conforming youth upon whom animus-based peer harassment is perpetrated suffer an array of serious, negative outcomes. Among other results, "experiences [of peer-to-peer student violence] are related to increased substance use, ... mental health problems, and sexual risk-taking behavior."²⁹ The Institute of Medicine reports that sexual minority youth who are targeted by peers are also at risk for suffering academic outcomes, such as diminished school attendance and low grades.³⁰

Sexual minority youth appear to engage in an array of risky behaviors at higher rates than do their heterosexual peers. The June, 2011 analysis of multi-state, multi-year Youth Risk Behavior Surveillance System high school student data performed by the U.S. Department of Health and Human Services' Centers for Disease Control and Prevention found that, "[c]ompared with students who are not sexual minorities, a disproportionate number of sexual minority students engage in a wide range of health-risk behaviors."^{31,32} Sexual minority youth, as the CDC Report indicates, also face heightened risk of substance use and abuse, including tobacco,³³ alcohol,³⁴ and illegal drugs.³⁵ In addition, as did the Institute of Medicine, the Centers for Disease Control and Prevention found that sexual minority youth appear to engage in risky sexual behavior at disproportionate rates.³⁶

The research fails to show a link between any *per se* weakness in a homosexual orientation and a particular vulnerability to negative outcomes from peer-to-peer student violence. Rather, as discussed in detail by Drs. Herek and Meyer, it appears that the extra pressure created by structural stigma is responsible for such disparate outcomes to the extent that they appear to exist.³⁷

Stigma impacts both the stigmatized and the stigmatizer. The Institute of Medicine reports that:

[c]ontemporary health disparities based on sexual orientation and gender identity are rooted in and reflect the historical stigmatization of [lesbian, gay, bisexual, and transgender] people. Most [lesbian, gay, bisexual, and transgender] people encounter stigma from an early age, and this experience shapes how they perceive and interact with all aspects of society.... Likewise, heterosexual people ... have been socialized in a society that stigmatizes sexual and gender minorities, and this context inevitably affects their knowledge and perceptions of lesbian, gay, bisexual, and transgender] people.³⁸

Unfortunately, the structural stigma which fuels much of the school-based harassment that sexual minority youth experience may compound their vulnerability to negative outcomes when it emanates from within the student's home. Structural stigma can be expressed as family rejection of the youth's minority identity. Family rejection theory appears to be validated by meta-analysis which shows that sexual minority youth are 1.2 times more likely than their heterosexual peers to be physically abused by their parents.^{39, 40} The heightened risk for parental abuse and other manifestations of family rejection appear to fuel the alarmingly high rate of homelessness among sexual minority youth.⁴¹

Sexual minority youth are also apparently at particularly high risk of re-victimization by schools and the legal system. Such students also appear to be:

1.25 to 3 times more likely than their heterosexual peers to receive punishment from schools, police or courts. ... [T]his greater likelihood of punishment is not explained by greater engagement in troublesome behaviors and suggest that LGB youth may be targeted for punishment or that mitigating factors such as self-defense may be overlooked.⁴²

Recent statistics indicate that roughly thirteen percent of youth responding to an anonymous survey study in juvenile detention facilities in six cities were sexual minority and gender-nonconforming youth.⁴³

The most egregious impact of animus-based peer-to-peer harassment, obviously, is the possible fueling of victims' suicidal ideation and behavior.⁴⁴ The Centers for Disease Control and Prevention's recent analysis of behaviors related to suicidality indicates that gay, lesbian, and bisexual high school students are roughly two to three times more likely than their heterosexual peers to have "seriously considered attempting suicide",⁴⁵ or to have "made a suicide plan."⁴⁶ This analysis further found that gay, lesbian and bisexual are approximately three to four times more likely than their heterosexual peers to have actually attempted suicide,⁴⁷ and that sexual minority youth are in the range of three to four times more likely than heterosexual students to have "made a suicide attempt that resulted in an injury, poisoning, or an overdose that had to be treated by a doctor or nurse."⁴⁸ The reasons that sexual minority youth may experience suicidal ideation and/or acts in response to victimization are not entirely clear. Nonetheless, social stigma may well drive some number of these experiences.⁴⁹ According to the Institute of Medicine, "[f]amily rejection due to sexual orientation may also be associated with increased risk of suicidality."⁵⁰ The need to intervene as fully as possible to diminish peer-to-peer bullying, harassment, and violence against sexual minority and gender non-conforming youth is not driven only by the need to improve targeted students' short-term quality of life and academic success, but also by indications that the negative consequences of such acts can follow the target students into at least young adulthood.⁵¹

Finding #8: Peer-to-peer bullying, harassment, and violence targeted toward sexual minority youth who are also racial or ethnic-origin minorities are serious, pervasive, and involve unique complexities which merit further, careful study.

Sexual minority youth who are also members of racial or ethnic-origin minorities, according to research, face particular vulnerability to peer-to-peer bullying, harassment, and violence and to their negative outcomes. The Commission has been advised that, "[i]n addressing the experiences of sexual minority students of color, it is important to recognize the intersectionality of identities and to avoid using an additive approach, i.e., examining race and

sexuality separately without addressing their intersection.”⁵² According to the Institute of Medicine, “[a]s highlighted by the concept of intersectionality, the experience of being a sexual minority is influenced by an individual’s other identities. Thus, the experience of being lesbian, gay, or bisexual appears to vary according to the racial or ethnic group with which one identifies.”⁵³

Given the limitations in obtaining probability samples of sexual minority youth and racial minority overall, as discussed in Finding #9 below, it is reasonable to assume that obtaining such samples of sexual minority youth who are also racial minorities would be particularly difficult. Therefore, given the absence in its record of probability studies or a meta-analysis regarding this specific population, it is reasonable to rely upon carefully-crafted non-probability studies conducted by highly-credentialed researchers and published in highly-respected journals. The studies of this nature which are in the Commission’s record demonstrate the heightened need to protect, as appropriate under the law, such youth.

One relevant study demonstrates that, as compared with white non-Latino/a peers and Latina sexual minority youth peers, young sexual minority Latinos face the highest rates of family rejection to disclosure of their sexual orientation. This high-rate rejection appears to be tied to sexual minority Latino youth, as compared to sexual minority white non-Latino/a peers and sexual minority Latina peers, having the highest rates of current depression, suicidal ideation, suicide attempts, heavy drinking, substance abuse-related problems, unprotected sexual activity, and diagnoses of sexually transmitted diseases.⁵⁴

Finding #9: The USCCR Report utilizes social science data which is rooted in conventional and legitimate research standards.

As self-report data collection techniques were first being developed, social scientists questioned their baseline reliability. Nonetheless, “[d]uring the 1960s, researchers began to recognize the true potential of the self-report methodology.”⁵⁵ Motivated by this understanding, researchers have since then discerned and implemented many ongoing improvements in the realm of self-reporting data collection. “[C]onsiderable attention has been paid to the development and improvement of the psychometric properties of the self-report method.”⁵⁶ Thereby, “[t]he self-report methodology [thereby] continues to advance, both in terms of its application to new substantive areas and the improvement of its design.”⁵⁷ This evolution has lead to researchers’ increased confidence in the reliability and validity of data collected by self-report.⁵⁸

Given the increased understanding that has lead to ongoing refinements of self-report data collection methodologies, it is now the case that:

the self-report method appears to behave reasonably well when judged by standard criteria available to social scientists. By these criteria, the difficulties in self-report instruments currently in use would appear to be surmountable; the method of self-reports does not appear from these studies to be fundamentally flawed. Reliability measures are impressive and the majority of studies produce validity coefficients in the moderate to strong range.⁵⁹

Whether the data is generated by self-report or otherwise, the methodology of the study creates different tiers of reliability of data.

Probability studies (those based upon as random a sample pool as possible) published in peer-reviewed journals with rigorous pre-publication standards are, overall, considered to be more reliable than studies based upon non-probability (non-random) sample pools published under the same circumstances. The Institute of Medicine explains that “peer-reviewed journals are the gold standard for the reporting of research results,”⁶⁰ and that “every effort [should be made] to consult works published in major research journals.”⁶¹ Within the realm of such studies, one should give “the greatest credence to such sources that report... research employing rigorous methods, were authored by well-established researchers, and were generally consistent with scholarly consensus on the current state of knowledge.”⁶²

Probability sampling among the some of the youth populations under examination by the Commission is particularly difficult to utilize. According to the Institute of Medicine,

[o]btaining a probability sample of a relatively small population, such as a racial, ethnic, religious, sexual, or gender minority, requires considerably more resources than are required for sampling the population as a whole. This is the case because a large number of potential participants must be screened to obtain a sample of minority group members large enough for statistical analysis. Still more resources are required to collect samples that permit study of subpopulations within these groups, such as socioeconomic, age, and geographic groupings, and comparisons of respondents according to health-related characteristics. Lacking such resources, relatively few studies designed specifically to examine LGBT individuals have been able to utilize large probability samples.⁶³

Therefore, most specifically with regard to sexual minority and gender non-conforming youth, “[p]robability sampling has seen limited use in the study of LGBT health. ... [T]he relatively small size of LGBT populations, the lack of research funding, and the sensitivity of questions relating to sexual behavior and gender expression have been barriers to effective probability sampling.”^{64,65} Despite the difficulties inherent in conducting probability studies about the sexual minority and gender non-conforming youth populations, however, relevant and reliable research is still possible to conduct and valid conclusions are still possible to draw.⁶⁶ Overcoming the inherent potential shortcomings in non-probability studies, aggregation of studies and meta-analysis are valid:

approach[es] to obtaining a national probability sample with a sufficient number of sexual- and gender-minority respondents involves combining data across studies. For ongoing studies that recruit new probability samples on a regular basis, it can be possible to combine sexual- and gender-minority respondents across years to produce a sample that is sufficiently large for analysis, provided that the studies all include comparable measures of key variables.⁶⁷

The Institute of Medicine notes further that:

[c]ombining data from multiple samples can be helpful in researching groups (like sexual and gender minorities) that represent a small domain in part of a larger survey. Because the numbers of these small groups often are not sufficiently large for analysis, combining data from multiple samples allows researchers to generate more accurate estimates.⁶⁸

Finding #10: The Commission found that “[c]urrent federal civil rights laws do not provide the U.S. Department of Education with jurisdiction to protect students from peer-to-peer harassment that is solely on the basis of religion,” and that “current federal civil rights laws do not protect students from peer-to-peer harassment that is solely on the basis of sexual orientation.” In addition, current state-level anti-bullying laws neither protect all students nor provide them with equal and consistent levels of protection.

The Anti-Defamation League has argued that, although most states have some form of anti-bullying statute in place, these statutes are very different in content. Further, none appear to address all identified areas in which coverage would be appropriate to fully protect students across the country. Such dimensions of an ideal law would include the required creation of school district policy, provision of a model policy, addressing the unique questions presented by cyberbullying, listing enumerated categories of protected students, mandating the definition and implementation of reporting procedures, implementing of parental notification requirements, provision of staff training, and imposition of accountability regarding districts’ reporting to the states.⁶⁹

The Anti-Defamation League has drafted a comprehensive model statute in this domain entitled “Cyberbullying Prevention Law.” Culling the best provisions from existing state laws across the country, this law seeks to address, in concise fashion, the relevant concerns.⁷⁰

Finding #11: A school district “neutrality policy,” “sexual orientation curriculum policy,” or any directive which precludes staff from discussing issues related to homosexuality, inappropriately chills school staff members’ ability to communicate with students and their families about peer-to-peer bullying, harassment, and violence related to students’ real or perceived sexual minority or gender non-conforming status. By doing so, such a policy facilitates the unchecked perpetration and negative impact of such peer-to-peer behavior.

Commission witness Ms. Tammy Aaberg provided detailed and compelling testimony regarding the July, 2010 suicide of her fifteen year-old, openly gay son Justin Aaberg.⁷¹ According to Ms. Aaberg, Justin’s suicide was fueled by the verbal and physical anti-gay harassment to which peers subjected him at school.

Justin Aaberg attended school in Minnesota’s Anoka-Hennepin School District No. 11, which has in place a “Sexual Orientation Curriculum Policy,” which is known colloquially as the “neutrality policy.” This directive states that:

[t]eaching about sexual orientation is not a part of the District adopted curriculum; rather, such matters are best addressed within individual family homes, churches, or community organizations. Anoka-Hennepin staff, in the course of their professional duties, shall remain neutral on matters regarding sexual orientation.⁷²

Reportedly, serious and pervasive problems of peer-to-peer bullying, harassment, and violence pervade District No. 11’s high schools as a result of the discriminatory implementation of this policy. In *Doe, et al. v. Anoka-Hennepin School District No. 11*, federal court plaintiff students and former students allege suffering years’ worth of unrelenting verbal and physical harassment from multiple student perpetrators due to the implementation of the Sexual Orientation Policy and a policy which preceded it.⁷³

In addition to the pending federal court action, Anoka-Hennepin’s Sexual Orientation Curriculum Policy is facing federal executive branch scrutiny as well. The U.S. Department of

Education and the U.S. Department of Justice are investigating allegations of discriminatory peer-to-peer harassment based upon gender non-conformity as related to the Sexual Orientation Curriculum Policy and Title IX.⁷⁴

The number and degree of reported acts of peer-to-peer bullying, harassment, and violence perpetrated against sexual minority and gender non-conforming youth, in tandem with the wide-ranging and serious consequences suffered by the targeted students, certainly raise questions about the implementation of Anoka-Hennepin District No. 11's Sexual Orientation Curriculum Policy. If, in fact, the policy and/or the manner in which it is implemented facilitate the creation of an illegally hostile environment for sexual minority and gender nonconforming youth, this situation exemplifies an unacceptable outcome to the failure of state and local authorities to control peer-to-peer harassment problems. If this is true, the situation underscores the need for students in Minnesota and across the country to have meaningful and consistent protections such as those proposed by the ADL Model Statute discussed above.

Finding #12: Potential federal tools for the further amelioration of peer-to-peer bullying, harassment, and violence have been introduced into the U.S. House of Representatives and the U.S. Senate. The Safe Schools Improvement Act, the Student Non-Discrimination Act, and a proposed amendment to Title VI of the Civil Rights Act of 1964 seek to close gaps in existing law and provide strong, viable protections for students at risk of victimization due to their sexual minority or gender non-conforming status or their religion.

As the Commission found, students targeted for peer-to-peer bullying, harassment, and violence only on the basis of their sexual minority or gender non-conforming status, or only to their religious affiliation, do not have the benefit of federal protections. The underlying problems are serious and pervasive. Further, the lack of consistency among state laws demonstrates the need for federal legal protections. The Commission's record and Report make clear that specific federal legislative protection for these students is warranted.

The Safe Schools Improvement Act (hereinafter "SSIA") is a cogent, targeted bill that seeks to ameliorate this gap for students targeted due to religion and sexual minority and gender non-conforming status that has recently been introduced into the U.S. House of Representatives and the U.S. Senate. The SSIA would amend the Safe and Drug-Free Schools and Communities Act. With bipartisan backing in both chambers, it seeks to address the targeting of students based upon, among other characteristics, race, national origin, sexual orientation, gender identity, sex, and religion. The SSIA would require federally-funded local educational agencies to adopt specific anti-bullying and anti-harassment prohibitions. It would further mandate that schools notify students, families, and school staff about prohibitions, incident reports, and complaint-registering information, and require that states collect and report to the U.S. Department of Education data regarding the nature and extent of the problems.⁷⁵

U.S. Representative Linda T. Sanchez (D-CA), lead U.S. House of Representatives sponsor of the SSIA, notes that "[t]he widespread nature of this [peer-to-peer student bullying and harassment] problem justifies federal action, especially where different schools, districts, and states have failed to address it."⁷⁶ The SSIA, if enacted, would,

help school personnel meaningfully address bullying and harassment and would ensure that States and [school] districts maintain and report data regarding incidents of

bullying and harassment in order to inform the development of effective federal, state, and local policies that address these issues.⁷⁷

A second relevant pending bill, the Student Non-Discrimination Act (hereinafter “SNDA”), is tailored more specifically to address the needs of sexual minority and gender non-conforming youth and those who associate with them. This Act, which enjoys bipartisan support in the U.S. House of Representatives, seeks to ban the exclusion of sexual minority and gender non-conforming youth from any activity receiving federal dollars. The SNDA would grant a cause of action to those who assert violation of their rights under the Act, and would waive states’ Eleventh Amendment immunity from such suits.⁷⁸

U.S. Senator Al Franken (D-MN), lead sponsor of the SNDA in the Senate, believes that:

[e]qual protections are needed for [lesbian, gay, bisexual, and transgender] youth, and they are especially warranted in the realm of education, which, according to the U.S. Supreme Court in *Brown v. Board of Education*, is arguably the most important governmental function. For parents of [lesbian, gay, bisexual, and transgender] students, public schools are currently failing to meet their most fundamental obligation to them: to keep their children safe. To combat the urgent problem of anti-[lesbian, gay, bisexual, and transgender] bullying, the government and public must strive to provide a safe and secure environment for all students, an environment in which all students have an opportunity to reach their academic potential without being held back by fear.⁷⁹

The SNDA does not seek to invent a new rubric for the recognition and protection of the right of sexual minority and gender non-conforming youth. Rather, as Sen. Franken notes,

the SNDA would provide meaningful remedies (potential loss of federal funding and a private right of action) for discrimination in public schools. Fifty years of civil rights history shows that similar laws that contain such remedies are often effective in preventing discrimination from occurring in the first place. Like other civil rights laws, SNDA would prompt schools to avoid liability by taking proactive steps to prevent the discrimination and bullying of students protected by the bill.⁸⁰

The lead co-sponsors of the SNDA in the U.S. House of Representatives, Rep. Jared Polis (D-CO) and Rep. Ileana Ros-Lehtinen, believe that in-school discrimination against sexual minority youth and those who associate with them is “a civil rights matter of great importance requiring an urgent, cooperative response from the federal government,”⁸¹ and that, given the scope, complexities, and importance of the issues, “school districts must be motivated to end discrimination and harassment against [sexual minority] students.”⁸²

Finally, H.R. 6216, as introduced into the 111th Congress, sought to amend Title VI of the Civil Rights Act of 1964⁸³ by adding the provision that “[n]o person in the United States shall, on the ground of religion, be excluded from participation in, be denied the benefits of, or be subjected to discrimination under, an educational program or activity receiving Federal financial assistance.”⁸⁴ This protection against religious discrimination, clearly, would be more appropriately expansive than the protections which the Safe Schools Improvement Act seeks to provide solely in the educational context.

Recommendations

Recommendation #1: Involved federal agencies, including the U.S. Department of Justice and the U.S. Department of Education, should provide funding for additional research into the seriousness, pervasiveness, and impact of peer-to-peer bullying, harassment, and violence, including cyberbullying, targeted toward students due to their race, national origin, sex, disability, religion, and/or sexual minority or gender non-conforming status in schools in the United States.⁸⁵

Recommendation #2: Additional scholarly research should examine with as much specificity as possible the issues of seriousness, pervasiveness, and impact of peer-to-peer bullying, harassment, and violence for students targeted due to their race, national origin, sex, disability, religion, and/or sexual minority or gender non-conforming status.

Recommendation #3: The U.S. Department of Education and other relevant agencies should assist school districts in providing information to students and their families about the modalities, including cyberbullying, through which students target each other for bullying, harassment, or violence due to race, national origin, sex, disability, religion, and/or sexual minority or gender non-conforming status.⁸⁶

Recommendation #4: As the Centers for Disease Control and Prevention of the U.S. Department of Health and Human Services recommend, “[e]ffective state and local public health and school health policies and practices should be developed to help reduce the prevalence of health-risk behaviors and improve health outcomes among sexual minority youths. In addition, more state and local surveys designed to monitor health-risk behaviors and selected health outcomes among population-based samples of students in grades 9-12 should include questions on sexual identity and sex of sexual contacts.”⁸⁷

Recommendation #5: Federal law enforcement agencies should collaborate with state and local law enforcement to ensure that the protections afforded under the Matthew Shepard and James Byrd, Jr. Hate Crimes Prevention Act to victimized students are, in fact, utilized fully and appropriately (including the requirement for collection of data regarding hate crimes both perpetrated by and against juveniles).⁸⁸

Recommendation #6: State governments should consider, as appropriate, either enacting anti-bullying statutes of the type put forth in the Anti-Defamation League’s Model Statute “Cyberbullying Prevention Law” or amending their existing anti-bullying statutes to conform with the parameters of this Model Statute. Localities and school districts would be well-advised to contemplate the comprehensive facets of this Model Statute when considering their own laws, regulations, and policies.⁸⁹

Recommendation #7: School districts should ensure that they are in compliance with federal laws and U.S. Department of Education guidance documents regarding the protection of students targeted for discriminatory peer-to-peer violence.

Recommendation #8: School districts should ensure appropriate training to enable staff to recognize and act to minimize students' animus-based behaviors toward each other.

Recommendation #9: School districts should provide to student victims and their families information about how to report incidents of violence, harassment and bullying, and how to enforce their rights, in a manner which is not unduly complicated, and which is written at a level (and in a language) easily comprehensible to students and their families.

Recommendation #10: School districts should ensure that the families of students are informed, in a timely manner and one which is respectful of student safety,⁹⁰ when their children are subject to violence, harassment and bullying at school. Such parental notice may be especially important with regard to disabled students who are victimized, as these students may be unable to report the abuse to their families if unaided by school officials. This notice should be in language and manner comprehensible to the family, especially in the case of Limited English Proficiency families.

Recommendation #11: School districts should rescind existing "neutrality policies," "sexual orientation curriculum policies," and any directives which preclude or chill staff from discussing issues regarding homosexuality with students and their families, thereby allowing peer-to-peer violence, bullying, and harassment against sexual minority and gender non-conforming youth to go unaddressed.

Recommendation #12: Congress should enact, and the President should sign into law, the Safe Schools Improvement Act for the benefit of students targeted for peer-to-peer bullying, harassment, and violence due to race, national origin, sex, disability, sexual orientation, gender identity, or religion.

Recommendation #13: Congress should enact, and the President should sign into law, the Student Non-Discrimination Act for the benefit of students targeted for peer-to-peer bullying, harassment, and violence due to their sexual minority or gender nonconforming status.

Recommendation #14: Congress should enact, and the President should sign into law, an amendment Title VI of the Civil Rights Act of 1964 to prohibit discrimination on the basis of religion.

Conclusion

There can be no doubt that peer-to-peer bullying, harassment, and violence against students due to their race, national origin, sex, disability, religion, and/or sexual minority or gender non-conforming status are serious and pervasive problems in the United States. Anti-minority stigma, which allows bias to linger in society, appears to complicate and compound the issues.

I commend the efforts of the U.S. Department of Justice and the U.S. Department of Education to enforce existing federal civil rights laws for the benefit of targeted students who fall under their protection. The federal government should extend these protections to students targeted due to their religion or sexual minority or gender non-conforming status by enacting bills such as the Safe Schools Improvement Act, the Student Non-Discrimination Act, and amendment to the Civil Rights Act of 1964.

Overall, the problems of peer-to-peer bullying, harassment, and violence exact far too high a cost. All of us, government officials, social scientists, educators, and families alike, must put forth our best efforts to continue to define, understand, and resolve the issues at hand. Honoring the memories of Justin Aaberg and the other youth whom we have lost requires no less.

Dissent and Rebuttal Statement of Commissioners Gaziano and Kirsanow, with Which Commissioner Heriot Concurs

Overview

Rather than undertake a critical analysis of what the U.S. Departments of Education (ED) and Justice (DOJ) are doing right, wrong, or could do better with respect to their enforcement of federal civil rights laws regarding peer-to-peer harassment, the report gets lost in the emotion over K-12 "bullying" generally. The report quotes a number of advocates and even some federal agency officials about the supposed bullying "pandemic" sweeping K-12 schools, but that type of rhetoric is to be expected from those who believe it is their job to promote the issue.

Unfortunately, there is no data whatsoever in the Commission's report that relates to K-12 schools' observance of or failure to follow the federal laws that deal with the subject, so there is no data whatsoever in the report that would support any change in law. There is also no serious analysis of the legal and policy issues raised by the agencies' current enforcement efforts. The cursory discussion of whether ED's recent guidance and DOJ's current interpretation of the relevant anti-discrimination provisions are unlawful and/or misguided does not fairly capture the competing arguments nor come to any conclusions.¹ Even in the absence of any data on the federal enforcement effort, we think some of ED's and DOJ's enforcement positions are inconsistent with law and seriously mistaken as a matter of civil rights policy.

An Analysis-Free Report

Pursuant to the Commission's organic statute, the purpose of its annual enforcement report is to study and critique the effectiveness of federal agency efforts to enforce one or more of the existing civil rights laws, but no serious attempt was made to critique the effectiveness of ED's or DOJ's efforts in the Commission report. The apparent purpose of this report is to condemn social behavior that includes teasing, eye-rolling, and exclusion among K-12 students. Yet, even if the report was an attempt to describe the negative social behavior of 6- 18 year-old students that it often misleadingly labels "bullying," its uncritical reliance on flawed surveys, advocacy group claims, and a mish-mash of contradictory statistics does more to mislead than cast light on the matter. Congress expects the Commission to exercise a higher level of professionalism in the social sciences. We regret that the Commission failed to live up to this expectation.

Since its creation, a central purpose of the Commission has been to "gather facts instead of charges" and "sift out the truth from the fancies" in the hopes of providing findings and recommendations "which will be of assistance to reasonable men."² To do so requires the Commission to be a careful and neutral arbiter of the competing (and sometimes complex) facts, issues and policy considerations at work. It can only accomplish this goal by avoiding the hype that the broader topic of bullying evokes (even if the enforcement agencies have not been as careful). Responsible and critical analysis is necessary to avoid ill-conceived policy recommendations or enforcement actions that have negative, unintended consequences.

The general topic of student teasing, bullying, and social exclusion is not within this Commission's jurisdiction. Even so, the Commission's report provides no reliable indication of whether any such behavior is on the rise, has declined, or has stayed about the same over time. The advent of social technologies alone is not an indicator that bullying is on the rise. Even if it is, the only matter relevant to the Commission's study of federal civil rights laws is whether K-12 schools are responding as they should when they learn of severe and pervasive acts of bullying on the basis of protected classes that rises to the level of legally actionable harassment under the civil rights laws enforced by ED's Office for Civil Rights (OCR) and DOJ.

There also are significant statutory, First Amendment, and practical issues worthy of more careful and detailed discussion throughout the report rather than the cursory fashion in its last chapter. The issues involved in student-on-student harassment are not simple. Though it is emotionally appealing for some to join the chorus that a larger federal role would somehow bring the number of bullying incidents among 55 million K-12 students significantly down, the Commission must refrain from doing so absent more careful, detailed analysis.

Irrelevant, Unreliable, and Conflicting Data

Putting aside the heated rhetoric about a bullying "pandemic," there is no data at all in the Commission's report on the subset of school bullying that is covered by federal law, *i.e.*, that which rises to the level of legally-prohibited harassment of federally protected classes. Thus, there is no data on the central issue for a federal civil rights enforcement report, namely, whether K-12 schools are adequately addressing their responsibilities under federal law, or for that matter, bullying more generally. Instead, many pages of the report are devoted to reciting highly questionable and conflicting studies and surveys to suggest that teasing and bullying generally is "widespread." It has been so for centuries, but the data in the report probably does more to mislead than illuminate policymakers regarding its nature, seriousness, or frequency.

To identify potentially relevant data, it is first necessary to understand what is and is not prohibited under federal law. Schools that accept various types of federal funding are themselves forbidden from discriminating on the basis of race, color, national origin, gender, and disability, but their liability for peer-to-peer conduct is understandably more limited. Although the relevant legal standards are not discussed in detail until Section 7 of the Commission's report, student conduct only creates liability for schools under federal law if: (1) they have actual notice of and are deliberately indifferent to (2) severe, pervasive, and objectively offensive conduct on the basis of race, color, national origin, gender, or disability (3) that creates a hostile environment having the effect of depriving victims of the educational opportunities of the school.³

Putting aside for now the conflicting interpretations of the civil rights statutes at issue, it is undisputed that schools are not liable under federal law for trivial student-to-student insults, acts of exclusion, or speech protected by the First Amendment, even if motivated by the victim's race, color, national origin, gender or disability. Moreover, K-12 schools are not generally liable under federal civil rights law even for severe and pervasive taunts or bullying that focus on the victim's weight, attractiveness, or other non-federally protected categories. Any decent school would try to prevent all types of harmful bullying, but K-12 schools simply are not liable under federal law for all bad, or even objectively cruel and persistent, student conduct.

Surveys or studies that lump all incidents of student teasing, acts of exclusion, spreading rumors, and other protected speech with more serious and sustained conduct that is violent or might constitute physical threats are not helpful in assessing a school's responsibility under federal law for two reasons. First, most conduct in such global surveys is not covered by federal law. Second, it is even less clear whether the schools responded appropriately to any or all of the conduct at issue. If schools are responding reasonably, there is no federal issue.

Unfortunately, there is absolutely no data in the report on the following critical matters relevant to the enforcement of the federal civil rights laws:

- (a) the frequency or amount of student-to-student bullying based on federally protected criteria that is severe, pervasive, and objectively offensive enough to constitute prohibited harassment under federal law for any relevant time period (*i.e.*, that which denies the relevant students' educational opportunities);

- (b) the frequency or amount of such federally prohibited peer-to-peer harassment in subparagraph (a) that K-12 schools did know (or should have known) about and took, or were alleged to have taken, insufficient action to address;

- (c) the frequency or number of claims captured in subparagraph (b) that were meritorious for any relevant time period;

- (d) the frequency or number of instances of harassment in subparagraph (b) in which federal enforcement agencies played more than a tangential role in resolving.

The above data would be critical in assessing even a snapshot of the relevant student conduct at issue, whether K-12 schools are responding appropriately, and the federal enforcement agencies' current efforts or involvement in enforcing the federal laws. However, policymakers might want even more data before venturing to change federal law. For example, policymakers might want data on the following:

- (e) a breakdown of such data for subparagraphs (a) and (b) for each class of students protected under federal law (e.g., severe and pervasive bullying that constitutes prohibited harassment based on race, color, national origin, gender, disability, failure to conform to stereotypes regarding the same); and

- (f) data that show changes in subparagraphs (a), (b), (c) and (d) over relevant time periods (e.g., five- or ten-year intervals or any other relevant time periods).

The actual data from ED and DOJ in the Commission's report does little or nothing to shed light on relevant questions for a federal enforcement investigation. The type and number of complaints received by OCR (set forth in Section 3 of the report) conveys no helpful information about schools' compliance with federal law as it relates to peer-to-peer conduct. The report concedes that the percentage of such complaints that involve peer-to-peer conduct is unknown. Even assuming the peer-to-peer complaints were identified, there is no information on what percentage of complaints were meritorious, or even marginally well supported. There is also no information on how many of the well-supported claims involved serious and pervasive conduct such that they might have constituted federally prohibited harassment. Finally, for the unknown subset that might be serious, meritorious complaints of peer-to-peer harassment, it is unclear whether the schools had taken or were already taking appropriate action.

The Commission's own review of OCR voluntary resolution agreements between 2005 and March 2011 is also virtually meaningless, for similar reasons. It is perhaps interesting but

hardly significant to learn that 138 of the 292 agreements examined relate to peer-to-peer conduct. But the Commission's examination of these voluntary agreements did not disclose anything else of particular value. For example:

- There is no analysis of the variation in the cases per year, which peak at 36 nationwide in 2009 and decline to 29 in 2010.
- There is no evaluation of how many complaints were either serious or meritorious. It is not very telling to voluntarily resolve a non-meritorious complaint.
- There is no information indicating how many of the roughly 23 schools per year that were the subject of such voluntary resolution agreements were already taking action on their own to resolve the dispute before OCR became involved.
- Assuming the schools at issue were not already taking action to resolve the dispute, there is no evaluation of whether the schools at issue responded immediately and voluntarily to claims brought to their attention or whether OCR played a more substantial role in resolving the dispute.
- There is no context to suggest how many thousands of schools are covered by federal law, the ratio of meritorious to non-meritorious complaints, or their relation to the actual incidence of serious bullying.
- Reliable estimates suggest there are approximately 55 million students enrolled in K12 schools in any given year.⁴ Yet, California and Missouri were the only states with more than ten resolution agreements with OCR over the six year period. The vast majority of states and DC had schools with two or fewer such agreements over the six-year period: Alabama, Louisiana, Michigan, Minnesota, Mississippi, North Carolina, Oregon, South Dakota, Tennessee, and Utah (with 2 each); Alaska, DC, Florida, Idaho, Maine, Montana, New Hampshire, New Mexico, Rhode Island, Vermont, Washington, and West Virginia (with one each); and Arkansas, Delaware, Indiana, Iowa, Nebraska, Nevada, New Jersey, North Dakota, South Carolina, Virginia, Wisconsin, and Wyoming (with none).
- Thus, the above listed states and DC had, at most, one or two of their schools or school districts enter into a voluntary resolution agreement with OCR in the six-plus year period. Many of the complaints may have lacked merit and were resolved for that reason. The report does not say. Some schools might have already been investigating and resolving the incident. The report does not say. Some schools might have been happy to learn of the complaint and voluntarily taken appropriate action. The report does not say.

Although the Commission's review of voluntary resolution agreements tells us nothing about the seriousness or merit of the complaints or anything about the schools' voluntary responses thereto, it does undercut DOJ's and other activists' hyperbole about a "pandemic" of bullying. Even if all were serious and meritorious complaints, zero, one, or two incidents in a given state over six years is probably not what most people would consider a "pandemic."

The Commission's report does not disclose what effort, if any, was undertaken to obtain the relevant data described above, despite our frequent requests for it. Yet the report should at least have disclosed that in response to questions from several commissioners at the briefing on May 13, expert witnesses expressed their belief that no reliable data exists on the most contested issues, including peer-to-peer harassment on the basis of sexual orientation or

failure to live up to a perceived gender stereotype, and accordingly, that no consistent frame of reference exists of this type of conduct over time.⁵ This is an inconvenient truth that should be honestly reported.

The final bit of relevant information that the Commission should have tried to obtain and analyze is what efforts K-12 schools are taking to comply with their obligations under federal law, or more generally, what they are doing to respond to all types of bullying. No serious discussion or analysis exists in the Commission report regarding these state and local efforts. Forty-nine states and the District of Columbia, and many more local jurisdictions, have formal anti-bullying laws and policies.⁶ Moreover, all states punish violence or threats of violence that advocates claim they are most concerned about, and every school likely has policies against other types of bullying, even if they are not contained in "anti-bullying" laws.

On pages 74 and 76, the report recites two activists' claims that the states' anti-bullying laws are "not working," but there is not even a casual examination of this assertion. Do the advocates think all teasing or bullying must stop for the laws to "work?" If so, what makes them think more federal laws would work? For example, every state prohibits theft with severe penalties, but thefts still occur. Does that mean state theft laws are "not working?" Would a general federal theft law prevent them?

The advocates' dismissal of state and local efforts to combat bullying deserves more attention than a he-said/she-said, few-sentence coverage in the report. It goes to the heart of the federal government's jurisdiction and the practical question of whether schools are doing a reasonable job enforcing the federal civil rights laws. Unfortunately, there is no quantitative or other objective evidence in the Commission's report that state and federal laws are not adequate.

Instead of highlighting the failure of ED and DOJ to keep or provide relevant data, the report attempts to mask this serious shortcoming with a plethora of irrelevant, unreliable, and oddly conflicting survey data on mean student behaviors. The Commission has the responsibility to sort the "truth from the fancies" and place them in context. The Commission should not simply re-publish unreliable and misleading statistics gathered from whatever source. The Commission should have investigated competing factual claims and analyzed conflicting data. Instead, the report too often recites various statistics, many of which are unreliable, misleading, or inherently suspect. Accordingly, the report is more hortatory than analytical.

To add injury to this social science insult, the report declines to endorse any definition of bullying, see page 2, yet quotes three that may be mistakenly understood as Commission-endorsed definitions.⁷ Even worse, it expressly refuses to evaluate the validity of any of the surveys or studies it cites (see the report at footnote 10). During our initial review of the draft report in May, we urged the Commission staff to evaluate all the surveys and studies cited in the report and delete all those that were irrelevant or unreliable or to at least note the deficiencies in those that are cited. Instead of doing so, the disclaimer appeared in the final draft report that the Commission did not "independently verify the data" and that some experts "critique the usefulness and accuracy of this data." Indeed.

Here are just a few examples of the problems with the data cited in the report.

- 1) Many of the surveys suffer from serious self-selection bias, as well as other obvious biases, including that the students could volunteer to respond to poll questions on an advocacy group or other website.⁸ As one study cited in the report notes about

sampling, "in contrast to probability samples, the sampling error associated with population estimates derived from nonprobability samples cannot be computed, and the extent to which the sample represents the population from which it was drawn cannot be known."⁹

- 2) The report cites one study that not only used a self-selected sample gathered from community-based groups and internet sites for LGB youths, but the students surveyed were from the United States, *Canada and New Zealand*.¹⁰ Citing a study of foreign students illustrates the throw-anything-against-the-wall approach to data in the report.
- 3) Different surveys relied on inconsistent definitions of the bad student behavior at issue, and none attempted to isolate the conduct covered by federal civil rights laws. Some surveys included exclusion "from activities on purpose," "spreading rumors," "influencing relationships," mild forms of teasing, and other conduct protected by the First Amendment.¹¹
- 4) Surveys administered in schools may not have the same selection biases, but are unreliable for other reasons. For one thing, self-reporting, particularly with broad and ambiguous categories, is notoriously problematic, as pointed out by an expert whose work is relied upon in the Commission report.¹² Moreover, many such school surveys are not voluntary; when adolescents and teens are forced to do something, they often rebel. In short, students who are repeatedly required to answer such surveys have a tendency to make things up, especially when the subject relates to sexual behavior.¹³
- 5) Due to a combination of such problems, the survey results were wildly contradictory, at least as set forth in the report. For example, 2% of the students in the SCS-NCVS survey supposedly reported being subject to hate-related words based on gender in a given year. Report at 8. The AAUW survey of students in grades 8-11 reported that 81% of students reported experiencing sexual harassment. Report at 11. Another survey of sexual harassment cited on page 8 claims the figure is 11%. No explanation is given for this wide divergence.
- 6) The AAUW survey also reported that boys were 33% more likely than girls (12% versus 9%) to claim that they had been forced to do something sexual other than kissing. That result seems, at best, counterintuitive. Report at 10. There are several possible explanations for the discrepancy, including poorly designed questions, selection bias, and boys who like to confound researchers with poor survey controls.

There are many other examples of irrelevant and unreliable data. After pages of citation to such data, it is not enough that there is a sentence admitting that some of the student behavior cited is not "necessarily" covered by federal civil rights laws. Report at 5. The Commission should have examined every factual claim and study, eliminated misleading or unreliable data, and retained only that which was reliable and has a close connection to our examination of ED/DOJ enforcement of the federal civil rights laws.¹⁴

Moreover, repeating and crediting others who claim that bullying is widespread or a "pandemic" without any quantitative support is misleading. How widespread? What constitutes a pandemic? What does Gregory Herek mean by "pervasive," which has a legal meaning? The Commission should have either credited or refuted such conclusions after carefully analyzing the reliable data or not used such loaded and contested terms.

Finally, even for the broader category of mean behavior, there is no reliable data that the relevant conduct is increasing, decreasing, or remaining about the same. It is necessary to have

a baseline and consistent data over time to form any meaningful conclusions about whether there is a bullying "pandemic." Trends relating to ill-defined behavior in nonscientific polls are not helpful. Even more important, we want to know if schools are more or less responsive to such incidents over time. The Commission report contains no information on that whatsoever.

OCR's Attempt to Expand Its Authority Through Creative Interpretation

Title IX prohibits schools receiving federal funds from discriminating on the basis of sex. Because students are not agents of the schools and the schools cannot exert the same control over them that even employers can exercise over their employees, the Supreme Court has made it clear that schools are not responsible under Title IX and analogous civil rights laws for all student acts. In *Davis v. Monroe County Board of Education*, the Court held that private damages actions may be brought against schools under Title IX for failure to remedy student-on-student sexual harassment, but "only where [the schools] are *deliberately indifferent* to sexual harassment, of which they have *actual knowledge*, that is so severe, pervasive, and *objectively offensive* that it can be said to *deprive* the victims of access to educational opportunities or benefits provided by the school."¹⁵ The Court's limitations on school liability was a logical and reasonably necessary interpretation of Title IX because students are not themselves state actors whom Congress can directly regulate and schools exercise only limited control over them, during specific times and settings, and do not know everything students do and say.¹⁶

ED's Dear Colleague Letter of October 2010 reads Title IX and other civil rights provisions in a manner that would greatly expand the scope of school liability compared to the legal standard in *Davis*. For example, ED changes the first prong of what constitutes prohibited harassment that schools are responsible for preventing from that which is "severe, pervasive, and objectively offensive" to that which is "severe, pervasive, or persistent."¹⁷ *Davis* uses the conjunctive "and" to require that all three conditions be met: that the conduct be serious, common, and offensive to an objective person. The Supreme Court specifically stated that one incident cannot give rise to liability.¹⁸ Under OCR's and DOJ's interpretation, including Jocelyn Samuels's testimony before the Commission, schools can be in violation of Title IX based on a single student act if the government believes it is sufficiently severe.¹⁹ OCR's formulation could also cover mild but "persistent" teasing by one student of another. OCR's interpretation might also capture dozens of different playground comments by dozens of different children if that rendered them "pervasive." Thus, the intentional switch from the Supreme Court's conjunctive phrasing to the disjunctive phrasing by OCR and DOJ broadens schools' potential liability enormously.²⁰

Further, OCR omits the term "objectively offensive" from its formulation of the legal standard, potentially removing a "reasonable person" protection. The Foundation for Individual Rights in Education (FIRE) warns in its public comment:

The loss of the crucial "reasonable person" standard means that a school's most sensitive students effectively determine what speech is prohibited. The "reasonable person" standard is a critical guard against punishing speech based solely on subjective (and possibly unreasonable) listener reaction— something that courts have repeatedly held unconstitutional over the years.²¹

OCR's answer to this charge—that its policy is to "consider the conduct from both a subjective and objective perspective"—is not reassuring.²² It is unclear why OCR omitted the "objectively offensive" factor, but OCR has not issued any further clarification since FIRE and others have pointed out the problem.

In the second harassment prong, OCR replaces the Supreme Court's requirement that the harassment "*deprive* the victims of access to educational opportunities or benefits provided by the school" with the almost infinitely broad "*interfere with or limit* a student's ability to participate in or benefit from the services, activities, or opportunities offered by a school."²³ The *Davis* standard is closer to the work-place harassment definition, which requires a fundamental transformation of work conditions;²⁴ the new OCR definition includes almost any slight. What range of teasing does not "interfere with" a student's "ability to ... benefit from [some specified] service, activit[y], or opportunit[y]" the school offers?²⁵

OCR also changes the notice requirement from "actual knowledge" to "knows or reasonably should have known."²⁶ The "actual knowledge" requirement recognizes that the antidiscrimination law is not directed at students but at schools, and schools without knowledge of the harassment cannot be responsible for it.²⁷ OCR essentially argues that since its enforcement actions are only prospective, it provides the necessary notice to the affected school districts and it would not threaten the loss of federal funding if the school agrees to take remedial action it deems appropriate. Although there is some logic to this distinction in theory, the guidance letter itself is not clear that prior unknown incidents cannot result in a loss of federal funding by themselves. Indeed, the "reasonably should have known" formulation implies otherwise. We also are concerned with the degree of leverage the "should have known" formula allows OCR in practice to insist on remedies it deems appropriate for such previously unknown incidents.

OCR and DOJ defend their many deviations from the legal standards articulated by the Supreme Court by distinguishing between a private suit for damages, as in *Davis*, and OCR's administrative enforcement actions, in which no damages are sought. OCR argues that the "standards established" in *Gebser* and *Davis* "are limited to private actions for monetary damages."²⁸ Quite true, but that doesn't mean that "anything goes" in the administrative enforcement setting. Moreover, the only meaningful administrative power ED has is to deny school districts federal money. It seems counterintuitive to argue that the courts read a statute narrowly to protect a school district from paying a one-time money damage award that is remedial, but allow ED to read the same law as expansively as it wants, based on the same conduct, when the consequence could be the permanent loss of all federal money.

Professor John Eastman's testimony before the Commission questioned the lawfulness of ED's and DOJ's interpretation in the Dear Colleague Letter. He explained that an administrative agency does have some discretion to implement a statute but that such discretion is not without limit: "An agency can impose regulations that are ancillary to the enforcement of a statute authorized by an enumerated power, such as rules requiring the reporting of certain data that is necessary to determine compliance with the underlying statute, but it cannot make up new prohibitions and substantive requirements that are not part of the relevant statute." He further explained that "the deviations between [ED's] 'Dear Colleague' letter last October and the *reasonable* interpretation of the relevant civil rights statute[s] are large."²⁹ In essence, an agency cannot vastly expand the reach of the statute in the guise of administering it.

Another of ED's purported distinctions is that the money damages in litigation are for retrospective wrongs. Since the administrative remedy is for a prospective failure to take the

remedial action OCR deems appropriate, ED argues no school actually has to lose its federal money. All it has to do is change its conduct. Yet, that doesn't quite answer the underlying substantive question either. If a robber says, "Give me your money or your life," that is a prospective choice. No one needs to lose his money, because he can give his life, and vice versa. But the robber doesn't have the substantive right to ask anyone to make that choice, prospective or not. Thus, if OCR has no statutory right to ask for certain actions/remedies based on the underlying conduct (perhaps because it was based on a single incident), it hardly matters that the threat to turn off the flow of money is prospective.

OCR does not indicate what the limits on its enforcement standards are if it is not bound by *Davis*. Pursuant to regulation, could ED condition funding on school districts agreeing to prevent harassment based on a child's weight or perception of what an ideal body mass index should be? The regulation would arguably be in furtherance of enforcing anti-discrimination laws, especially if OCR argued that many perceptions of ideal body mass were linked to gender stereotypes. Yet, we believe such a hypothetical regulation would be an unreasonable interpretation of Title IX, which doesn't cover "lookism" directly or indirectly. Such an unreasonable interpretation would not be entitled to deference by the courts under prong one of the *Chevron* doctrine.³⁰ Professor Eastman's conclusion that OCR's current interpretation of Title IX is unreasonable seems equally correct, and thus is unlikely to be granted deference or upheld by the Supreme Court.³¹

Gebser v. Lago Vista Independent School District is not to the contrary. Agencies have authority under comparable funding laws to investigate compliance and establish procedures consistent with due process for its revocation, but they have no authority from Congress to change the underlying substantive standard of what constitutes discrimination the state entity must follow.³²

When the National School Boards Association pointed out in a letter to OCR how far it had departed from the *Davis* standards, OCR could have answered that the standards are meant to be identical or that it would change them to mirror *Davis*. But it did not do so. Instead, OCR argued that its harassment standards are "consistent" with *Davis*, even if the "terms" and "words" are "in some ways different." According to OCR, the Supreme Court's and OCR's "definitions are contextual descriptions intended to capture the same concept."³³ It is risible to argue that standards that are "in some ways different" are still "consistent" as long as both are "contextual" standards. Under that postmodern reasoning, any standard that is "contextual" is "consistent" with any other "contextual" standard. What about the following harassment standard: "under all the facts and circumstances, might some kids feel bad"? And if the standards are consistent, then why does OCR take pains to argue that its administrative standards defining harassment can be different from the standards in private suits for damages?³⁴

Finally, OCR argues that the legal standards set forth in the Dear Colleague Letter of October 26, 2010 are nothing new, and are essentially the same standards set forth in guidance since 1994.³⁵ This is not a defense if the guidance was never consistent with a reasonable interpretation of the statute. Moreover, Section 7 shows that OCR guidance has not been consistent over the years, hewing closer to *Davis* in 2001 (shortly after *Davis* was handed down), then departing further by 2010. The report acknowledges that "OCR's use of different terms in different documents can be confusing."³⁶ There is an easy way to resolve any confusion and maintain consistency, however, and that is simply for OCR to accept the *Davis* standard.

Serious First Amendment Concerns

For all of this report's limitations, it does at least acknowledge that OCR's Dear Colleague Letter poses thorny First Amendment questions that OCR does not satisfactorily answer. Both the report and a recommendation adopted by the Commission call for OCR to provide greater clarity to address the First Amendment concerns.³⁷ But the report notes these serious concerns only belatedly—this important discussion is relegated to the last 10 pages of the report—and in a way that gives far too much credit to OCR's assurances that very little of the harassment it sees implicates protected speech.³⁸

The Dear Colleague Letter does not engage the free speech questions everyone else notices. Its only references to the First Amendment are buried in footnote 8 and in its last pages, where the reader is simply directed to a link to OCR's 2003 Dear Colleague Letter on the subject. All the 2003 guidance document does is affirm quite generally that OCR does not intend for schools to restrict students' constitutionally protected speech. Neither it nor the current Dear Colleague Letter addresses how schools are to negotiate real-world conflicts.

As briefing testimony and public comments revealed, the threat ED's guidance poses to constitutionally protected speech is not hypothetical. The guidance will quite predictably lead school districts to overreact and trample students' freedom of expression by adopting various zero-tolerance approaches to curb "offensive" speech in an effort to avoid lawsuits and compliance investigations by OCR.³⁹ The guidance also creates an incentive for school districts to single out for special disfavor certain kinds of speech because of its unpopularity or political incorrectness.⁴⁰ These concerns are worthy of far greater exposition, far earlier in the report⁴¹ and with far less deference to ED's presumed good intentions.

As a preliminary matter, no one seriously disputes that schools have broad authority to restrict (or that they should restrict) unruly conduct, including some speech, in school when that conduct or speech either has created actual disruption of school activities or is likely to cause a "substantial disruption of or material interference with school activities."⁴² Schools should attempt to prevent and punish threats of violence and acts of vandalism. Particularly as it relates to classroom discussion, schools can also bar the use of vulgar, lewd or indecent terms⁴³ as part of their pedagogical mission, as well as speech that advocates illicit drug use.⁴⁴ While they cannot penalize students based on the viewpoints they articulate, schools can insist that students take care to express themselves appropriately and constructively, without profanities or epithets, for example. As Professor Volokh noted, schools may even express criticism of or condemn rude and hurtful (albeit constitutionally protected) speech.⁴⁵

Schools *should* control substantially disruptive behaviors both to ensure that no student is denied educational benefits and to further the educational purpose of guiding students to become decent human beings who can interact in a civilized fashion with others—even those they disagree with or dislike.⁴⁶ These are settled propositions and nothing in this statement should be construed to suggest otherwise. The problem with the Dear Colleague Letter (and with ED's and DOJ's attempt to federalize the issues of bullying and harassment more broadly) is that its proscriptions extend far beyond the type of classroom settings referenced above, and it ignores that even offensive speech in the classroom may be protected by the First Amendment.⁴⁷

It is much less likely that schools can establish that non-threatening student speech uttered between classes, during lunch, or before or after school (even if unkind) is as likely to cause a disruption of the educational mission—and thus is subject to the same degree of regulation—as classroom discussion. The Supreme Court has rejected arguments that certain topics at

certain settings are so sensitive that they may be subject to broad viewpoint regulation.⁴⁸ This is true regardless of the age of the speakers involved.⁴⁹ It has also rejected blanket bans by schools on all "offensive speech."⁵⁰ It is even less likely that schools can make the case that student speech outside the school (on the Internet, for example) poses the same risk of disruption to the school's activities, and thus, is subject to constitutional regulation.⁵¹

OCR's guidance acknowledges none of these important distinctions. Indeed, it applies a standard of liability to schools that would allow ED compliance reviewers to make after-the-fact determinations that schools "should have known" (rather than had actual notice) that student exchanges in these non-classroom settings were somehow contributing to a hostile environment. ED has adopted a view that essentially requires schools to be hyper-vigilant arbiters of any instances of student interaction that might give rise to hurt feelings.

Throughout the course of the briefing, various proponents of ED's aggressive approach sought to reassure us that the free speech problems identified by no less than five witnesses (and a fair number of additional public comments) were a "red herring."⁵² They insisted that the only conduct they are really concerned with does not actually involve speech at all, except when it amounts to physical threats or creates a reasonable fear of physical harm.⁵³ Instead, they asserted that their (and by extension ED's and DOJ's) focus is on actual physical harm like assault, rape, or other violence⁵⁴ that are outside the scope of First Amendment protection.

To paraphrase a line from Professor Volokh's oral testimony before the Commission, we wish that were true.⁵⁵ The Dear Colleague Letter also covers a broad array of non-threatening speech. The advocates' assurances that it does not cover such protected speech ring hollow for the reasons identified by Professor Volokh in his written and oral testimony, which is even summarized in the body of our report.⁵⁶ If the advocates were correct that liability for verbal harassment was essentially limited to physical threats, Assistant Secretary Ali should have said so when she responded to the NSBA letter from Mr. Negron, or in written or oral testimony provided to the Commission. We find it significant that she did not do so and that no one at OCR or DOJ has disavowed the broad language of the guidance letter that explicitly includes non-threatening speech.

Moreover, those few who attempt to defend the OCR's legal position seem fixated on two extreme positions on the First Amendment, neither of which we endorse. The first is the fictitious, First Amendment absolutist position that kids always have a right to say whatever they want in school,⁵⁷ which is a straw man. It has not been taken by any of us or anyone we are aware of who has participated in this debate. The second extreme position is the one actually taken by some school districts: that students have *no* First Amendment rights. For example, the two school principals sued in *Morgan v. Swanson* and their government-funded attorneys took the position in court (still pending) that the Constitution "does not prohibit viewpoint discrimination against religious speech in elementary schools" and that First Amendment free speech claims could not be brought by elementary school students.⁵⁸ They maintain these positions through years of litigation even though the Supreme Court has consistently held since *Barnette*, in 1943, that the First Amendment applies to public school children,⁵⁹ and that public school students do not "shed their constitutional rights to freedom of speech or expression at the schoolhouse gate."⁶⁰ OCR's Dear Colleague Letter fails to address the real problem of school officials, like these in Texas, who misunderstand what the Constitution requires. Our concern is that the short shrift given to the First Amendment in the Dear Colleague Letter will actually lead to more illegal censorship like that in *Morgan*.

We find the Dear Colleague Letter's imposition of responsibility on schools to police cyberbullying to be quite revealing of OCR's position on the potential scope of school liability for non-threatening student speech. "Cyber-bullying" has no set meaning beyond what its detractors declare it to mean. As best we can surmise, it seems nothing more than a derogatory label for electronic speech that someone else doesn't like. This open-ended "cyber-bullying" largely occurs off-campus and after school hours, in such electronic media as private Facebook postings, emails, text messages, G-chats, and YouTube videos. Its potential to create school liability is a stark example of OCR's policy overreach and lack of concern for First Amendment freedoms.

As the General Counsel for the National School Boards Association observed:

If schools are to be held accountable for all bullying behavior that may constitute harassment under federal civil rights laws, including that which takes place in cyberspace but makes its way onto campus overtly or by effect, schools will understandably feel the need to patrol electronic communications by students. But taking on this burden may be an act of futility, for how can a school patrol private internet sites with any measure of effectiveness? And yet the "should have known" standard would suggest that schools must police such venues to avoid liability under the OCR enforcement standard. The current confusion among courts as to what off-campus behavior can be regulated by schools, combined with the OCR enforcement position, results in an untenable expectation that schools police off-campus online behavior while ultimately facing liability for conduct over which they have no control.⁶¹

It is highly unlikely, though admittedly not impossible, that a bully would transmit an actionable physical threat via email, chat or text, because even teenagers are aware that creating a record of such a physical threat could result in their arrest or other serious punishment. Instead, our record reflects that the "cyber-bullying" concern is that electronic means would be used to perpetrate the following categories of conduct the anti-bullying activists want to stamp out: "spreading rumors," "interfering with relationships," and disparaging the target's physical or personality traits in an attempt to make them feel badly about themselves. We do not condone such conduct, but the First Amendment does not only protect speech most people like.

The First Amendment problems with ED's guidance are only exacerbated by its expansive theory of school liability and multiple examples of conduct that it asserts constitute actionable harassment under the civil rights laws. (See the previous section of this statement for more on OCR's erroneous legal standard of liability.) "OCR is creating an expectation that school officials are to respond to each and every offensive incident as if it were a civil rights violation."⁶² The practical effect of the Dear Colleague Letter is that Title IX will be used to foist a federally-imposed general civility code on schools and students across the country.

Consider ED's application of its erroneous standard that any "severe, pervasive or persistent" conduct could create a hostile environment. Although single-incidents could not create an actionable hostile environment under the legal standard articulated by the Supreme Court, under ED's current enforcement stance, it is possible for "one-offs" to create liability if they are sufficiently severe.⁶³ Thus, it is not difficult to imagine how administrators could think that even pure expression, if deeply offensive, might contribute to a hostile environment and so try to regulate it.

Similarly revealing of the intended scope of ED's guidance is its imposition of liability on schools for not sufficiently addressing a "hostile environment" or "hostile school climate." ED's

current guidance defines harassment to include speech such as graphic and written statements, and such statements need not be directed at a specific target. Thus, ED's definition of harassment is not restricted to insults directed at a particular individual. It also includes general statements, such as statements critical of homosexual conduct or particular religions.

Drs. Herek and Meyer testified about their theory that the mental health of gay students is negatively affected by the stigma and prejudice of society towards homosexuality, which will at times be expressed in the form of speech. General derogatory statements by students will be taken as evidence by OCR that a school has permitted an environment hostile to gay youth. Taken logically, that means that constitutionally protected speech expressing or contributing to "stigma" must be regulated by schools to avoid liability for the allegedly hostile environment.⁶⁴ It might be very difficult for a school district to satisfy OCR's standards without proscribing all speech that can be construed as hostile to gay youth. Similar examples have been borne out in litigation.⁶⁵ ED must be aware that the issuance of such guidance will put schools in a catch-22. Yet, it also knows that schools are more likely to accept the risk of potential private lawsuits over the suppression of student free speech for nominal damages than they will be to cross regulators who control the purse strings of their federal dollars.⁶⁶

A number of witnesses at the Commission's May 13 briefing identified the difficult definitional and line-drawing problems the Dear Colleague Letter forces upon school districts.⁶⁷ Francisco Negron, General Counsel of the National School Boards Association, testified to the schools' very real concern over "the tension . . . between student freedom of expression and the regulation of hostile environment."⁶⁸ Unfortunately, schools have a track record of outrageous violations of students' freedom of speech. Hiram Sasser's testimony contains troubling examples of schools that are already taking a heavy-handed approach to non-disruptive speech involving students' belief in God and similar expressive conduct.⁶⁹ Such non-disruptive speech is routinely censored based on fear that it might cause offense to someone, somewhere.

The facts of *Morgan v. Swanson*⁷⁰ are just one example of the heavy-handed censorship many administrators already exercise to deny student speech. In that case, two principals were sued for clear religious viewpoint discrimination, and the students ultimately were vindicated, even though their claim for money damages has dragged on for many years, with the principals refusing to admit they did anything wrong after years of litigation. One principal prohibited kids from distributing "goodie bags" at a "winter break" party because the bags contained items with religious references, including pencils bearing the message, "Jesus is the reason for the season," and candy-cane pens with information regarding the Christian origin of the symbol. Another child was not permitted to give her friends tickets to a free Christian drama production at her church, even though she attempted to do so during non-curriculum time and with no material or substantial disruption to the school. The principal confiscated the tickets to the play, threatened to kick the child out of school and even threatened to have the child's parent arrested over the attempted distribution of such material, not because gift giving was inappropriate but because the play was religious in nature.

These are not isolated examples. Schools have attempted to prevent a Muslim student from wearing her hijab in class, have banned all religious items and certain Valentine's Day and Christmas cards because they were religious, and have even tried to prevent a kindergartner from praying over her snack with two classmates.⁷¹ In *Harper*, a high school student was interrogated and chastised by school personnel and security personnel, including one wearing a sidearm, that he "had to leave his faith in the car" because he wore a T-shirt with a Bible verse expressing his views against homosexuality during the school's "day of silence."⁷² The Dear

Colleague Letter, which lacks any accompanying guidance to schools regarding speech that they should not forbid, will only lead to more wrongful censorship and more litigation.

The Dear Colleague Letter's reference to system-wide training to combat a perceived hostile climate might also conflict with students' First Amendment rights. For example, it explains that it is insufficient for a school to recognize and respond to individual incidents on a case-by-case basis and only by punishing individual harassers. "Instead, school district [sic] must recognize and respond to a 'hostile environment' with a 'systemic response' 'reasonably calculated to end the harassment and prevent its recurrence.'"⁷³ The "systemic and comprehensive" actions the guidance contemplates include "training or other interventions not only for the perpetrators, but for the larger school community."⁷⁴ As Hiram Sasser noted in his testimony, to the extent that such training induces participants to affirm or agree with propositions that are contrary to their personal beliefs, such actions constitute compelled speech in violation of the First Amendment.⁷⁵

The report cites public comments by Erwin Chemerinsky and Stuart Biegel, who argue that those who have expressed concern about students' First Amendment rights should be comfortable with deferring to the judgment of school officials about how best to handle and classify offensive speech.⁷⁶ Yet, the enforcement agenda announced by ED and DOJ will chill most rational educators from instituting anything other than what the federal government instructs.⁷⁷ The hypotheticals will not be construed as optional "best practices"; they will become requirements. For schools that already censor too much student speech, the guidance will only add to the denial of student rights.

For all ED's protestations that its approach hews closely to established precedent and that it does not seek to supplant the judgment of school administrators, but to work closely and cooperatively with them, the policy's over-breadth betrays ED's true intent. Its efforts are likely to produce the precise effect on school districts that Justice Kennedy warned about in his dissent in *Davis*:

The only certainty flowing from the majority's decision is that scarce resources will be diverted from educating our children and that many school districts, desperate to avoid Title IX peer harassment suits [or compliance investigations], will adopt whatever federal code of student conduct and discipline the Department of Education sees fit to impose upon them. The Nation's schoolchildren will learn their first lessons about federalism in classrooms where the Federal Government is the ever-present regulator.⁷⁸

Unfortunately, we do not share some of our colleagues' confidence that ED's issuance of a new Dear Colleague Letter containing First Amendment guidance will be sufficient to cure the earlier Letter's infirmities or to stem the practical threats to protected speech. In part, that is because we do not think that protected speech is merely an accidental casualty here.⁷⁹ Treating all student taunts as potential civil rights violations may score political points with various favored constituencies, but it creates a host of thorny legal tangles that school districts and their attorneys, administrators, and students have to wade through. "Civil rights laws [and by extension the agencies that enforce them] do and should regulate conduct, barring employers or school officials from engaging in discriminatory practices. . . . But laws can't make people like each other; and laws can't force people to speak politely, civilly, or inoffensively, unless we aim for a world in which everyone is equal and no one is free."⁸⁰

Discrimination Based on Sexual Orientation Is Effectively Covered under Title IX

Title IX of the Education Amendments of 1972 prohibits public and private schools that receive federal money from discriminating “on the basis of sex.”⁸¹ In the employment context, the Supreme Court has held that discrimination-based sex stereotyping can violate Title VII of the Civil Rights Act of 1964, such as where an accounting firm would not promote a woman to partner because of her aggressiveness even though aggressiveness is a requirement for the job. This placed the woman in an “intolerable and impermissible catch 22” and thus constituted discrimination because of sex.⁸² The Supreme Court has also held that sexual harassment violating Title VII can occur where the harasser and victim are of the same sex.⁸³

ED acknowledges that “Title IX does not prohibit discrimination based *solely* on sexual orientation.”⁸⁴ This is a proper reading of the statute based on Congress’s original intent. As Roger Clegg put it, “‘sex’ does not mean ‘sexual orientation,’ and it certainly did not mean that in 1972.”⁸⁵ ED and DOJ further state that Title IX prohibits both offensive sex stereotyping, which includes harassment of boys or girls who don’t measure up to some notion of masculinity or femininity, respectively, and other forms of sexual harassment regardless of the students’ actual sexual orientation or perceived sexual orientation. Whether or not Title IX was intended to cover sex stereotyping, several lower courts have so held.⁸⁶

The analogy to *Hopkins* and *Oncale* is logical, and the courts are unlikely to narrow their interpretation of what has come to constitute sex stereotyping under Title IX.

Yet the report concludes that there is a gap in federal civil rights enforcement because harassment that is solely based on sexual orientation or gender identity is not prohibited, even though harassment based on sex stereotypes is prohibited. Report at 55. The report raises the specter that this “dichotomy may create a perverse incentive for alleged discriminators to evade Title IX liability by asserting that students’ harassment is based entirely on homophobic animus.” *Id.* But the report points to no evidence that schools are successfully avoiding liability by claiming that the harassment is based on sexual orientation.⁸⁷

ED told the Commission that it does not track complaints alleging discrimination or harassment based solely on sexual orientation, yet there is no evidence from ED or DOJ that there has ever been a complaint that presents a pure “sexual orientation” claim to track. Instead, ED claims it does not distinguish between sex harassment claims of heterosexual and LGBT students and whether they involve sex stereotyping. Report at 35. Thus, given the broad legal precedents, the likely student harassment scenarios, and the lack of contrary evidence, it seems quite doubtful there is a “gap” in federal enforcement authority as a practical matter, at least in the real world.

Unfortunately, four commissioners defeated attempts to clarify a finding that “federal civil rights laws do not protect students from peer-to-peer harassment that is solely on the basis of sexual orientation.” Such a finding can only mislead readers about the state of the law. Four commissioners rejected an amendment that would have added language at the end of the finding informing readers that ED, DOJ, and the courts have nevertheless interpreted federal civil rights laws “as protecting students from peer-to-peer harassment that is based on conforming, or failing to conform, to stereotypical notions of masculinity and femininity.”⁸⁸ The three of us voted for adding the clarifying language, with Gaziano noting that there is no evidence in the report of a single instance in which a harassment claim failed because it was based “solely” on the student’s sexual orientation. The three commissioners supporting the clarification did not propose to strike the finding adopted by the majority, but simply urged that it be made reasonably complete.

As adopted, the Commission's finding is highly misleading about ED's enforcement efforts and the current state of the law, even if a few instances of non-enforcement based "solely" on sexual orientation can be found. The current finding strongly implies there is *no* federal protection for students who are harassed or subjected to violence based on their nonconformity to sexual stereotypes, when all such sex stereotyping claims are cognizable, and there is no reason to think that many sexual minority students can make out one claim but not the other. No sensible reason was provided by the commissioners who rejected the clarification, and no substitute amendment was offered by them that would make the finding less misleading. As it is written, however, the finding serves the political agenda of those who seek to argue that an intolerable "gap" exists in the federal civil rights protection that must be filled with new legislation.

Even so, the pending bills mentioned in the report and most strongly supported by the advocates to address this issue do not merely close this alleged enforcement "gap." Instead, they impose many new requirements and cover much new ground that would have significant unintended consequences.⁸⁹ Such legislation should be evaluated on its own merits, or lack thereof. The supposed "gap" in Title IX coverage should not be used as an excuse to promote or disguise something much broader.

Rebuttal to Statements by Other Commissioners

As Commissioner Heriot explained in her accompanying dissent, three of us voted against the decision by the Commission's majority to abruptly cancel our ongoing enforcement report project for FY 2011, which was to investigate the DOJ's use of *cy pres* agreements. Given the Commission's sensible past practice in which a new majority sets the course for future studies but continues ongoing projects (especially those more than half-way completed), the cancelation of the *cy pres* study was highly unusual and inappropriate, regardless of the preference the new majority had to study something more to its liking this fiscal year.⁹⁰

We also objected to the decision in March of this year to launch and attempt to complete a competent investigation of the student bullying topic generally and the federal agencies' enforcement efforts relating thereto. We maintained that this particular topic could not be adequately investigated in a few months before the draft report had to be produced for review. We also objected to (and voted against) some of the timetables and procedures adopted to produce the draft report in such a short time frame. Our predictions that nothing meaningful could be completed on this topic in the time allotted have been proven correct, although our foresight was probably due more to our years on the Commission rather than anything else.

Putting aside those significant objections, however, we concur in Chairman Castro's description of the collegiality in which the briefing in May was organized, the constructive efforts (under the circumstances) of our career staff to deal with the short deadlines dictated by the shift in topic, and the fair-minded way in which Chairman Castro conducted the briefing. The failure of our career staff to conjure data that does not exist is understandable. Notwithstanding the serious substantive concerns with the report expressed in this statement, we especially appreciate the efforts Commissioners Achtenberg and Castro made to try to turn a sow's ear of an investigation into a silk purse report. That we believe their well-meaning efforts largely failed to produce what they hoped should not be interpreted as a lack of respect

for them personally. Indeed, we regret the necessity of pointing out several of our continuing disagreements with them below.

Is Greater Federal Involvement in K-12 Bullying Helpful or Counterproductive?

A. Leaps of Logic in the Concurring Statements

The accompanying statements by Commissioners Achtenberg, Castro and Yaki contain certain common assertions that incorporate a non sequitur and a related leap of logic. The non sequitur is that because bullying of various types is harmful (ignoring for now that there is absolutely no evidence whether the level of bullying has changed since the dawn of time), there is a need for greater federal involvement to solve the problem. The related leap of logic is that because various anti-bullying efforts at the state and local level are not uniform, there is naturally a great need for uniform national standards.

The concurring statements make no, or almost no, attempt to connect the dots on these non sequiturs and logical fallacies, yet their favored policy recommendations of increasing the federal government's involvement and passing more national laws do not logically follow from either premise. For example, Chairman Castro writes that there is evidence that students are being bullied because of their membership in protected classes, and "[w]hen that happens, I believe the Federal government has an important role to play."⁹¹ This is an illogical leap for several reasons. Students are not themselves state actors. Many instances of peer-to-peer bullying may not be known to school officials. More importantly, if the schools take adequate and appropriate steps to address bullying they reasonably become aware of, there is no federal issue. The Fourteenth Amendment prohibits state actors from denying equal protection of the laws to their citizens; it does not empower the national government to right all wrongs in the first instance, no matter how real. At a minimum, there must be substantial evidence in the record that states are systematically ignoring the rights of students in certain protected classes before greater federal intervention would be warranted. There is no such evidence.

There are many more serious crimes that occur "nationwide" that most people, even intuitively, know should not be federalized with uniform, national prohibitions. Murder and sexual assaults are devastating crimes, but states vary in countless significant ways regarding how they define the different levels of homicide, the type of sexual assault offenses, the age of consent for statutory rape, the penalties for each, and the criminal procedures for proving those different offenses and various defenses (insanity, for example). It's highly doubtful that federal preemption of homicide and sexual assault offenses would prevent more of them (for many of the same reasons we explain below relating to bullying), but it would be unconstitutional for the national government to try. For similar reasons, it probably would not help if Congress were able to supplement state laws with general, federal homicide and sexual assault statutes.

Unless one naively believes that all instances of teasing and mean behavior can be stopped among the 55 million American students, it is necessary to seriously analyze the efforts the schools are taking to address the issue. No attempt was made to do so in the Commission's report or the concurring commissioner statements. It also would be necessary to carefully analyze any additional efforts that might arguably improve the situation before leaping to the conclusion that the federal government could naturally do a better job. Better than what? What is the baseline? Assuming, *arguendo*, that it is simply a matter of increased resources and effort that is needed, why can't the local schools do more with those extra resources? Indeed, dealing

with DOJ and OCR attorneys and the rest of the federal bureaucracy, for example, will diminish the time principals, teachers, and administrators spend making their schools better.

Commissioners Castro, Achtenberg, and Yaki seem to assume that national, uniform standards are always better, without any explanation. They call for federal anti-bullying statutes because, as Commissioner Castro writes, “current state-level anti-bullying laws neither protect all students nationwide nor provide all students with equal and consistent levels of protection from state to state.”⁹² Yes, but so what? Most students only go to school in one state at a time. Why isn’t it enough that the state where any given student lives has laws that protect him or her? Moreover, the same legal characterization is true for murder, rape, and theft laws; there is no reason to fear that the lack of uniformity would cause a problem in prosecuting any particular case.

The District of Columbia and 47 states now have anti-bullying statutes, and two of the remaining three states have statewide anti-bullying regulations.⁹³ All states prohibit violence and threats of violence, regardless of the motive involved, which is what the anti-bullying activists and our fellow commissioners claim they are either exclusively or most concerned about. (That is also the most common understanding regarding their repeated references to “student safety.”) Moreover, the schools of every state and territory have the inherent ability and institutional history of addressing student bullying that pre-dates and supplements these specific anti-bullying laws and regulations. There is absolutely no evidence that particular states are deficient in enforcing such laws, regulations, and practices.

If the claim was that one or more of the states had deficient laws, regulations, or policies, that might support an argument for the particular state or states to reform their laws and practices. But neither the Commission’s report nor our fellow concurring commissioners’ statements analyzed the state enforcement record or made that argument. As the previous section of this joint dissent explains, we suspect the disconnect is at least partly because those who favor new federal legislation do so not out of a love of uniformity per se—or a coherent argument that uniformity provides better protections for students who go to school in only one state at a time—but because they want to provide additional power and responsibility to the national government for other reasons. Perhaps they have sincerely come to believe that the national government is the best, most effective level of government there is. We don’t share that view, but we think there are additional reasons to believe that increased federal intervention is likely to be counterproductive in this area that ED has admitted is “primarily a local responsibility.”

B. Reasons Why Greater Federal Intervention May Be Counterproductive

We previously noted that there is no relevant data relating to violations of the federal civil rights laws concerning student-on-student harassment; no relevant data, evidence, or analysis of ED’s or DOJ’s effectiveness in enforcing the relevant federal laws; and no helpful information or analysis regarding the efforts K-12 schools are undertaking to enforce either the federal laws or otherwise respond to student bullying or harassment generally. Yet OCR is attempting to greatly expand its authority in this area with legally erroneous “guidance,” which Commissioners Achtenberg, Castro and Yaki seem to support. We now offer a brief reflection on whether such expansion of federal authority is likely to help or hurt.

In addressing the question, we do not mean to impugn federal officials’ subjective motives for attempting to expand their power. It is human nature for federal officials, or anyone for that matter, to believe that expanding their power will do a world of good. Indeed, the vast majority

of individuals enter government service with the best of intentions, but it is also human nature for such officials to increasingly come to believe that the common good coincides with their self interest. The public choice literature shows that whatever serves to increase bureaucratic authority is a powerful predictor of what bureaucrats will seek, but it is not surprising that they rationalize their behavior and sincerely come to believe that they know what is best.

A serious study of *relevant* data on student-on-student harassment and schools' responses thereto might be necessary to definitively answer the question of whether more federal involvement would help or hurt in preventing bullying, but the following reasons should counsel against the lazy assumption that greater federal involvement is always better. And with regard to what even Assistant Secretary of Education Russlynn Ali conceded is "primarily a local responsibility," our analysis suggests that more federal involvement is quite likely to be counterproductive.

- First, increased federal pressure will inevitably increase the number of "zero tolerance" responses to alleged harassment with ridiculous results. As Commissioner Heriot pointed out in her accompanying dissenting statement, kids in preschool and kindergarten are already suspended or arrested too often for trying to hug their teachers or kiss their classmates.⁹⁴ But things can get worse. Even the Antioch College conduct code ridiculed on Saturday Night Live would not go far enough for current activists' tastes. At least the Antioch College code permitted one student to ask another whether he could hold hands, hug, or kiss his romantic interest.⁹⁵ Some activists now purport to define bullying to include "unwelcome" flirting,⁹⁶ which is hardly an aggressive act, and in any event, is preliminary to asking for a date. Will K-12 schools have to pass comprehensive new speech codes that prohibit "unwanted" date requests unless a student's Facebook status expressly welcomes all new date invitations? What other restrictions on sexual innuendo will be required? As Professor Volokh noted: "Romantic problems occasionally cause suicide. We don't go out there and start pervasively regulating romance because of that danger including a danger to teenagers."⁹⁷ Volokh's first point is undoubtedly correct, but a lot of activists would like to prove him wrong on his second point.
- Second, expanded federal authority to investigate incidents of K-12 school bullying will divert federal attention from the rare but serious cases in which a particular school or school district really is indifferent to protected-class-based violence. The troubling racial violence in a South Philadelphia high school explored by the Commission in its May 2011 briefing is a potent example.⁹⁸ It seems to us that DOJ should have been quicker to respond, especially since serious injury and potential loss of life was at play. Almost all schools do want to stop all forms of bullying, and it is not just because they fear liability for damages, although that is surely an additional incentive to follow the law. The massive resistance to desegregation in the 1950s-70s is not an apt analogy to instances of student-on-student harassment because there is no evidence that schools in general are indifferent to the serious incidents of harassment of any of their students. Nevertheless, the existing federal law, properly understood, provides an important backstop for race or similar class-based violence that a few schools might ignore. Helen Gym's testimony about the un-checked violence in Philadelphia at our briefing is cited as proof that the federal government should intervene to stop violence. We agree, but her testimony actually supports our view that there is a critical role for

federal officials when schools are deliberately indifferent or contribute to serious racial violence. Our fear is that this critical, but limited, role might get diluted or “defined down.” When DOJ and ED are busy policing offensive “eye rolling” or taking depositions about the tone of voice in which a compliment was offered, they divert resources and undermine respect for the more serious incidents of violence and harassment.

- Third, greater federal regulatory involvement to prevent teasing and the like that doesn’t rise to the level of what the Supreme Court defined as prohibited federal harassment will undercut the accountability local school officials and state legislators have to parents and students to prevent and address all types and degrees of bullying. The more the federal government acts as the savior, no matter how well meaning that may be, the more attention will be directed to Washington. It is hardly surprising that activists of all stripes focus their energy on federal action, but few consider whether that will backfire if the federal government is really unable to make a difference. Since few acts of bullying do rise to the level of a federal civil rights violation, this diffusion of responsibility will have a sadly counterproductive result. Local officials who should be responsible can partially evade their accountability by playing the blame game: “we are complying fully with the federal guidelines, and the feds haven’t provided enough money to combat the problems that overwhelm our schools.” This is hardly a trivial concern. Given the many thousands of local school officials involved, even a slight dilution in local accountability can have a larger impact than a corresponding increase in responsibility at the national level.
- Fourth, as Commissioner Heriot demonstrated in her accompanying dissent and we explained during the Commission’s May 13 briefing, 800-pound gorillas from Washington, DC tend to get their way, but their ways are not always best. One-size-fits-all rules and wrongheaded ideas from Washington may have various counterproductive effects. One unfortunate example is the recent, federal “school discipline” agenda, that could require less discipline for certain types of students who deserve it to prevent a “disparate impact.”⁹⁹ Moreover, 800-pound gorillas may not like local experimentation and local solutions.
- Fifth, one of the zero tolerance responses worthy of special note is that the “anti-bullying” indoctrination called for by many of the activists may violate freedom of conscience and actually teach intolerance, instead of meaningful tolerance of differing opinions.¹⁰⁰ One frequent reply to this concern is that sensitivity training need not require students to affirm anything they don’t believe. That is true in theory, but testimony from Hiram Sasser at our briefing suggests that forced indoctrination and intolerance are already too common in such supposedly “tolerance” building programs. For example, in *Harper v. Poway Unified School District*, 445 F.3d 1166 (9th Cir. 2006), *judgment vacated for other reasons*, 549 U.S. 1262 (2007) (mem.), a high school student was prohibited from wearing a T-shirt expressing his opposition to homosexuality since it ran counter to the school-sponsored “day of silence.” Judge Kozinski in dissent explained that the particular “Day of Silence” program was “a political activity that was sponsored or at the very least tolerated by school authorities.” The majority even quotes school administrators saying they were especially concerned about the T-shirt because it was being worn the day after the Day of Silence. In short, the student’s speech was banned because it was contrary to the schools’ recent program

of indoctrination on "tolerance." OCR's call for more of this training is likely to make matters worse.

Thus, on one side of the ledger is the absence of any evidence, or even a coherent argument, that greater federal involvement in preventing student-on-student bullying or harassment will help. Our thoughts above provide some important reasons to believe greater federal involvement will backfire, particularly as it undermines local accountability to address the real problems and leads to ridiculous results and increased denials of student freedoms.

Problems with the Data Cited in Concurring Commissioner Statements

According to the Commission's statute, our annual enforcement report is supposed to "monitor *Federal* civil rights enforcement efforts in the United States."¹⁰¹ Thus, this report should have focused almost exclusively on whether ED and DOJ are correctly interpreting the relevant federal anti-discrimination statutes, such as Title IX and Title VI, and whether they are taking appropriate actions against schools that are actually violating those statutes. The time spent in the report and concurring commissioner statements discussing the frequency of teasing, acts of exclusion, rumor mongering, and undefined bullying that does not violate federal law is largely off point, since those discussions tell us nothing about the federal government's enforcement of the relevant federal anti-discrimination laws, and whether schools are following federal law.

Another problem is that many of the studies cited in the report and relied upon by other commissioners combine survey terms such as "bullied, teased, or taunted"¹⁰² or "threatens or insults."¹⁰³ In each case, the less serious conduct is likely to be much more common, but the report treats them as if they are describing "violence" or, at the least, "bullying."¹⁰⁴ Even the use of the word "harassment" has a markedly different meaning depending on the context of the question and the type of respondent. A typical teenager might say "my parents harass me constantly to clean my room and get good grades" or "my teacher is always harassing me to do better in school." To a lawyer who litigates workplace sexual harassment cases, harassment has a technical, legal meaning. When teens are asked about harassing conduct by fellow students, it is very important to review how that question is asked, and no matter how the question is posed, teens are not likely to give the word "harassment" its legal meaning. For example, the California Healthy Kids Survey, relied on in the Commission's report for data on "verbal harassment on school property," asked students if there were any "mean rumors" or "lies spread about" them, or if they were "made fun of because of [their] looks" or the "way" they "talk."¹⁰⁵ Thus, as Commissioner Thornstrom points out, we must be very careful to look at the type of questions asked in these surveys and not jump to conclusions when the survey summary uses terms like "bullying," "harassment," and the like.

Commissioner Achtenberg dismisses such concerns for precision and our federal jurisdiction with a somewhat sweeping, general claim: "There can be no doubt that peer-to-peer bullying, harassment, and violence against students due to their race, national origin, sex, disability, religion, and/or sexual minority or gender non-conforming status are serious and pervasive problems in the United States" (emphasis added).¹⁰⁶ We have a sense that bullying is a serious issue for some schools, as it has been for decades, but exactly how serious and whether it is "pervasive" in any meaningful sense is entirely unclear. For example, there is no reliable data in the report or commissioner statements whether it is more or less pervasive in rural, suburban, or urban schools. We can venture a guess, but it would be just that. Do some states

do a much better job, such that bullying is not "pervasive" (which is itself a legally loaded term) in any of its districts? The report and concurring commissioner statements offer no clue on that important question.

The data cited in the report and in the concurring commissioner statements are so inconsistent and biased, based on self-reports and self-selecting non-probability samples, that we cannot often distinguish the possible reliable factoid from the worthless dross. That is why we urged the Commission to verify the studies it cited. As part-time commissioners, we did not have the time to do this ourselves, but the more we examine studies brought to our attention, the higher the percentage of worthless and misleading studies we think exists. Unfortunately, some of our fellow commissioners seem to have been too trusting, and by relying on the studies cited in the report and by advocacy witnesses, they have unwittingly undermined their own positions.

Commissioner Thernstrom's statement contains many of the same data criticisms that we document, and Commissioner Heriot not only concurs in this statement, her own dissenting statement raises similar criticisms. Thus, four commissioners—Gaziano, Kirsanow, Heriot and Thernstrom—have expressed serious concerns about the reliability and relevance of the data cited in the report. Even Commissioner Yaki acknowledges that the report suffers from an "inability to thoroughly scour the literature" and a "rushed timeline."¹⁰⁷ Commissioner Titus resigned from the Commission before the report or its findings were voted on, and her replacement, Commissioner Kladney, understandably abstained from voting on the report and almost all of its findings. Accordingly, only two of eight commissioners seem to express great confidence in the report's data, with double that number expressing grave doubts about its reliability and Commissioner Yaki staking out a middle ground. That level of distrust is telling in itself.

Despite Commissioners Achtenberg and Castro's efforts to sidestep the issue, there still is no data on whether bullying has increased or decreased over the past five, ten, twenty, or 10,000 years. Professor Eastman testified that bullying has gone on as long as there have been schools, and we bet it pre-dated the creation of schools by many millennia. Before policymakers increase federal intervention in this area, they should know whether bullying has increased or decreased over time. And if any increase is shown to be unrelated to the degree of federal intervention or negatively correlated, this would seriously undermine the case for more federal intervention.

Concurring commissioners' citation of the number of complaints received by OCR and DOJ adds nothing to nothing. OCR does not distinguish between peer-to-peer harassment and harassment by teachers or administrators. Thus, we do not know how many of the complaints relate to peer-to-peer harassment. We also have no idea how many complaints are meritorious. While OCR received 4,433 harassment complaints of all kinds from 2005 through 2011—out of approximately 55 million K-12 students—there were only 138 voluntary resolution agreements related to peer-to-peer harassment during this same six-year period. And a voluntary resolution agreement does not mean the school was deficient: a school may have adequately addressed the problem, and the agreement merely conforms to what the school has done.

We cannot address all our concerns with the other data relied upon in the concurring commissioner statements, but we will focus on a few areas of special concern. Commissioner Kirsanow offered the motion that added disability to the scope of the report, and we agree there is reason to suspect that disabled students may be more vulnerable to bullying and less likely to report it. Thus, the lack of reliable data with regard to bullying of disabled students is

particularly disappointing to us. Commissioner Achtenberg acknowledges “there has been ‘very little research’” with regard to bullying of students with learning disabilities,¹⁰⁸ yet the studies she cites are still highly problematic.

The report’s claim that 94% of parents of children with Asperger Syndrome report that their children had been bullied, citing a 2009 article by Susan Carter, is highly misleading. The 94% figure actually comes from an article by Little (2002) which is merely cited in the 2009 Carter article. Most importantly, the Little study reported on frequencies of bullying by “siblings and/or peers.”¹⁰⁹ Such a study tells us nothing valuable about peer-to-peer bullying in schools because the figures may be mostly describing more frequent sibling behavior in the home. (Despite our loving relationships with our siblings today, while growing up, few weeks would pass without bullying among our siblings. We would expect reports of 99% bullying by siblings who are close in age.)

The further claim that 65% of parents of children with Asperger Syndrome reported that their children had been victimized by peers, with 50% reporting their children were scared by peers, though this time produced by the Carter study, are still highly misleading. The Carter study, like the Little research, included bullying committed by “a brother or sister.”¹¹⁰ Sibling behavior in the home is beyond the control of schools. Such incidents do not implicate federal jurisdiction. The Commission should have carefully analyzed the details in this and the other studies before citing them in the report.

The report’s explicit disclaimer that much of the data cited in it are questionable does not absolve the Commission or commissioners for citing unreliable or misleading studies. Even given the rushed nature of the report, it is still surprising how many errors and misleading uses of data are contained in a couple of sentences in the report describing the Carter study, which we reviewed because another commissioner mistakenly relied upon the report’s citation to it. Such errors call into doubt claims made throughout the report about the frequency and severity of peer-to-peer bullying.

Even on its own terms, the Carter study has a number of limitations. The author herself noted several serious issues: Only 34 parents participated in the study, a “relatively small” sample size. The parents were not randomly selected, but were instead recruited “online, in clinics, and at autism conferences,” and “may not be representative of the true population.” Moreover, “parents may have exaggerated their child’s experiences of victimization and shunning.” Finally, “the reliability and validity of the both [sic] measures used are still being determined.”¹¹¹ Indeed, the Carter study from 2009 found significantly less victimization of students suffering from Asperger Syndrome than the Little study from 2002.¹¹²

In the first portion of this joint dissent, we also noted the dramatically contradictory surveys cited in the report on sexual harassment. Commissioner Achtenberg relies heavily on only one of them, the 2001 AAUW study in which 81 percent of students in grades 8 to 11 supposedly reported experiencing sexual harassment. The California Healthy Kids Survey of the California Department of Education, also cited prominently in the report, is administered to hundreds of thousands of public school students in grades 7, 9, and 11 in that state. Eleven percent of the respondents in the 2007-2009 survey reported being subject to harassment based on gender.¹¹³ The report cites both numbers as equally valid, even though the difference is a factor of seven. And only two percent of students reported in another study being targeted by “hate-related words” on the basis of gender.¹¹⁴ Such wildly divergent percentages should call all of them into question, but we previously noted other reasons to doubt the AAUW study.

The report and one of the concurring commissioners also claim that 800 incidents of rape or attempted rape and 3800 incidents of sexual battery that were not rape were reported by schools in the 2007-08 school year, according to ED's National Center for Education Statistics.¹¹⁵ Rape and sexual battery are serious crimes in all states and jurisdictions, and we hope all appropriate cases were the subject of a successful criminal investigation and prosecution, as warranted. Yet, as serious as those crimes are, some corrections and perspective are in order. The report wrongly says there were 800 incidents of rape reported by schools, when the underlying study it cites says there were actually 800 rapes *or attempted rapes* reported by schools.¹¹⁶ It would be helpful to know how broadly "attempted rape" is defined for this purpose. However it is defined, this mischaracterization of attempted rape as rape is yet another example of the rushed and erroneous way data is handled in the report. Second, given the number of preschool and kindergarteners who were cited for sexual harassment for hugging and attempted kissing in some school districts (see Commissioner Herriot's dissenting statement), we also wonder what type of conduct schools reported under "sexual battery." And finally, we need some baselines to put all such figures in perspective. There are about 55 million primary and secondary students. The rate of reported rape and *attempted rape* in the ED report was less than .05 per 1000 students and roughly 0.1 per 1000 students for sexual battery that was not rape,¹¹⁷ which is, according to our review of DOJ's Bureau of Justice Statistics website, a tiny fraction of these crimes for teens overall.

With regard to another category of students, Commissioner Achtenberg proposes to find that forty to fifty percent of sexual minority and gender non-conforming youth are subject to peer-to-peer bullying, harassment, or violence, citing the public comment of Professor Mark Friedman. As an initial matter, forty percent is half the 81 percent of all students reporting sexual harassment in the AAUW study. Moreover, the comparison of figures in Friedman's underlying article is not as striking as his comment to the Commission in which he summarized the results. Both the Friedman public comment and our report left out the results for heterosexual males and females, which put the numbers in some context.¹¹⁸ Moreover, the usual caveats about studies based on retrospective self-reporting apply, as even Friedman admits they "may be biased."¹¹⁹

But whatever the actual level of teasing, harassment, bullying, or other "bad" conduct, neither the report nor concurring commissioner statements show that local school districts across the country are failing to deal with such issues appropriately. If schools are acting reasonably, there is no need for an expanded federal role. There remains a need for the federal government to act swiftly, as in the South Philadelphia high school case where school officials appear to have been grossly negligent in the face of racial violence. Thankfully, such cases seem to be quite rare.

Sexual Minority Stress Theory

The minority stress theory, as described by Professors Herek and Meyer, is as follows: Sexual minority youth have no inherent physical or mental health problems relative to other youth. Yet, they have worse health outcomes, particularly mental health outcomes, which are most likely caused by societal stigmatization of homosexuality.¹²⁰ This theory may have some validity, though it has been questioned by other scholars. Ritch Savin-Williams (Department Chair, College of Human Ecology, Cornell University) has noted the significant, positive change in attitude of the American public toward gay individuals since 1995, which has greatly reduced social stigmatization of homosexuality.¹²¹ Lisa M. Diamond (Department of

Psychology, University of Utah) has questioned the importance of gay-related stress, pointing to “[e]vidence suggest[ing] that the average sexual-minority youth spends as much time ruminating about normative adolescent concerns such as love and romance as about gay-specific stressors such as hate crimes or familial rejection.”¹²²

Even if true, the minority stress theory is beside the point. Most of the examples cited by Commissioner Achtenberg, which certainly are troubling, are beyond the control of any school. She quotes from a report that “[c]ontemporary health disparities based on sexual orientation and gender identity are rooted in and reflect the historical stigmatization of [LGBT] people.”¹²³ Commissioner Achtenberg notes that families may reject a child due to his or her sexual identity and the structural stigma of homosexuality; there is a heightened risk of parental abuse; there is a higher rate of homelessness; gay youth face “heightened risk of substance abuse, including tobacco, alcohol, and illegal drugs;” police and courts might be biased against them (although could any disparities in punishment be due to their using alcohol and illegal drugs more?); and gay youth “appear to engage in risky sexual behavior at disproportionate rates.”¹²⁴ As cruel as parental rejection is, let alone parental abuse and the risky behaviors described above, this may easily swamp what goes on at school. The simple truth is that there is no study that reliably measures whether bullying at school on the basis of sexual orientation causes any particular, measurable degree of harm. It would be a very difficult effect to study, but perhaps in time there will be a way to measure it.¹²⁵

Moreover, students may disassociate themselves from others for all sorts of wrongheaded and mean reasons, but that does not by itself constitute “bullying” unless it is defined downward to include “acts of exclusion” that some activists are pushing for. It certainly does not implicate federal civil rights laws, and for a good reason. Neither the state nor the federal government is responsible for policing friendships. Government must not discriminate in its own right, but it is not liable for the historical stigmatization or bigotry held by individuals in society.¹²⁶
